# HARMONIC TOTALLY REAL MAPS OF THE 3-SPHERE INTO THE COMPLEX PROJECTIVE SPACES

ISAMI KOGA and YASUYUKI NAGATOMO

(Received July 8, 2024)

## Abstract

Applying a generalized do Carmo-Wallach theory based on a generalization of Theorem of Tsunero Takahashi, we classify harmonic totally real maps of the 3-sphere into the complex projective spaces. This means that we employ differential geometry of vector bundles with connections and construct the moduli spaces of those maps explicitly.

## 1. Introduction

The purpose of the present paper is to classify harmonic totally real maps with constant energy density of the 3-sphere  $S^3$  into the complex projective spaces  $CP^n$ . This work is motivated by Li's result on isometric minimal totally real submanifold  $S^3$  of  $CP^n$  [5], in which, he uses the Hopf fibration  $S^{2n+1} \rightarrow CP^n$  and a Theorem of Takahashi on isometric minimal immersions from  $S^3$  into  $S^{2n+1}$ . Instead of the original one, we apply a generalization of Theorem of Takahashi based on differential geometry of vector bundles and connections and a generalization of do Carmo-Wallach theory [6] which are reviewed in §2. In §3, we describe the (complex-valued) function space  $C^\infty(S^3)$  on  $S^3$  as an  $SU(2) \times SU(2)$ -module in a standard way ([2] or [8]). Then the spectral decomposition of the Laplacian emerges and the set of Hermitian endomorphisms on each eigenspace  $\mathcal{H}^k$  is decomposed into irreducible components in which the moduli space will be realized.

In §4, a generalization of Theorem of Takahashi relates maps under consideration to an eigenspace  $\mathcal{H}^k$  of the Laplacian. Then using  $\mathcal{H}^k$ , we introduce the standard map into  $\mathbf{P}(\mathcal{H}^{k*})$  which is an  $SU(2) \times SU(2)$ -equivariant desired map (Proposition 4.2). Then a generalization of do Carmo-Wallach theory requires a representation theoretic argument for an explicit construction of the moduli spaces (Theorem 4.4). At this stage, our approach (Proposition 4.3) is similar to that in Toth-D'ambra [8]. Indeed, we have the direct relation of results of [8] on moduli spaces of harmonic maps of  $S^3$  into  $S^n$  with constant energy density. Since those maps induce harmonic totally real maps with constant energy density of  $S^3$  into  $CP^n$  via the two-fold covering  $S^n \rightarrow RP^n$  and a totally geodesic and totally real embedding  $RP^n \rightarrow CP^n$ , our moduli spaces include those by Toth-D'ambra (Theorem 4.7). Following Li, those are called *absolutely real*. Li gave examples of absolutely real minimal submanifolds which are standard maps in our terminology. Furthermore, he also obtains a totally real submanifold of  $CP^{11}$  which is not absolutely real. We will show that the standard maps are unique  $SU(2) \times SU(2)$ -equivariant harmonic totally real maps with constant energy density of  $S^3$

to  $\mathbf{C}P^n$  up to image equivalence (Proposition 4.2). Finally, we will obtain harmonic totally real maps  $f_t$  with constant energy density parametrized by  $t \in [0, 1]$ . The map  $f_0$  is the standard map and the others are non absolutely real. The map  $f_1$  corresponds to a point in the boundary of our moduli space and is regarded as a map into  $\mathbf{C}P^{11}$ .

## 2. Preliminaries

**2.1. Vector bundles.** For a complex vector bundle  $V \rightarrow M$ ,  $\Gamma(V)$  denotes the space of (smooth) sections of  $V \rightarrow M$ . Then for each  $x \in M$ , we have a linear map  $ev_x : \Gamma(V) \rightarrow V_x$  called the *evaluation map* defined by  $t \mapsto t(x)$  for all  $t \in \Gamma(V)$ ,  $x \in M$ . (see, for example, [1, p.298]). If a (finite-dimensional) subspace  $W \subset \Gamma(V)$  is given, then the restriction of  $ev_x$  to  $W$  is also called the evaluation map which is denoted by the same symbol  $ev_x : W \rightarrow V_x$ .

Generically,  $\underline{W} \rightarrow M$  will stand for a trivial (complex) vector bundle with fibre  $W$  over a base manifold  $M: M \times W \rightarrow M$ . Thus the evaluation map is considered as a bundle map  $ev : \underline{W} \rightarrow V$ .

We assume that a vector bundle  $V \rightarrow M$  has a Hermitian metric  $h$  and a connection  $\nabla$  compatible with the metric  $h$ , for which we write  $(V \rightarrow M, h, \nabla)$  or  $(V, h, \nabla)$ . The curvature form of  $\nabla$  is denoted by  $R^V$ . In this article, a vector bundle  $V_1 \rightarrow M$  is said to be *isomorphic* to  $V_2 \rightarrow M$  if there exists a bundle map  $\phi : V_1 \rightarrow V_2$  such that  $\phi$  is an isomorphism of vector bundles preserving the metrics and the connections. Then  $\phi$  is called a *bundle isomorphism*.

**2.2. Geometry of Projective spaces.** Let  $\mathbf{C}^{n+1}$  be a complex vector space of dimension  $n+1$  and  $\mathbf{P}^n = Gr_n(\mathbf{C}^{n+1})$  the complex projective space of hyperplanes in  $\mathbf{C}^{n+1}$ . Then we have an exact sequence  $0 \rightarrow T^*(1) \rightarrow \underline{\mathbf{C}^{n+1}} \rightarrow \mathcal{O}(1) \rightarrow 0$  of holomorphic vector bundles over  $\mathbf{P}^n$  where  $T^*$  is the holomorphic cotangent bundle and  $\mathcal{O}(1)$  is the line bundle of degree 1. By using the natural projection  $\underline{\mathbf{C}^{n+1}} \rightarrow \mathcal{O}(1)$ , we can regard  $\mathbf{C}^{n+1}$  as a subset of  $\Gamma(\mathcal{O}(1))$ . By fixing a Hermitian inner product on  $\mathbf{C}^{n+1}$  the holomorphic cotangent bundle and  $\mathcal{O}(1)$  inherit metrics, and can be given the Hermitian connections (see, for example, [4, p.11, Proposition 4.9]). When the curvature 2-form of the Hermitian connection on  $\mathcal{O}(1)$  is denoted by  $R^{\mathcal{O}(1)}$ , the Kähler form  $\omega$  on  $\mathbf{P}^n$  is given as:

$$\omega = -\sqrt{-1} R^{\mathcal{O}(1)}.$$

Let  $f : M \rightarrow \mathbf{P}^n$  be a map. If  $f$  satisfies  $f^*\omega = 0$ , then  $f$  is called a *totally real map*. The real projective space  $\mathbf{R}P^n$  is realized as a totally geodesic and totally real submanifold of  $\mathbf{P}^n$ , which is the typical example. Following Li [5], when the image of a totally real map  $f : M \rightarrow \mathbf{P}^n$  is included in a totally geodesic and totally real submanifold  $\mathbf{R}P^n$ ,  $f$  is said to be *absolutely real*.

**2.3. Evaluation homomorphisms and induced maps.** Suppose that  $L \rightarrow M$  is a line bundle and consider a subspace  $W$  of  $\Gamma(L)$ . The line bundle  $L \rightarrow M$  is said to be *globally generated by  $W$*  if the evaluation is surjective. Under this hypothesis, there is a map  $f : M \rightarrow \mathbf{P}(W^*)$ , defined by  $f(x) := \text{Ker } ev_x = \{t \in W : t(x) = 0\}$ . The map  $f$  is called the *induced map by  $(L \rightarrow M, W)$* , or simply by  $W$  if  $L \rightarrow M$  is already specified.

**2.4. Maps satisfying the gauge condition.** Let  $f : M \rightarrow \mathbf{P}(W^*)$  be a smooth map. The map  $f : M \rightarrow \mathbf{P}(W^*)$  is said to be *full* if the induced linear map  $W \rightarrow \Gamma(f^*\mathcal{O}(1))$  is a monomorphism. When the line bundle  $\mathcal{O}(1) \rightarrow \mathbf{P}(W^*)$  is equipped with a Hermitian metric

$h^{\mathcal{O}(1)}$  and a connection  $\nabla^{\mathcal{O}(1)}$ , these are pulled back to a metric  $f^*h^{\mathcal{O}(1)}$  and a connection  $\nabla^{f^*\mathcal{O}(1)}$  on the pull-back bundle  $f^*\mathcal{O}(1) \rightarrow M$ .

We fix a complex line bundle  $(L, h, \nabla)$  over a manifold  $M$ . We will say that  $f : M \rightarrow \mathbf{P}(W^*)$  satisfies the gauge condition for  $(L, h, \nabla)$  if there exists a bundle isomorphism  $(L, h, \nabla) \cong (f^*\mathcal{O}(1), f^*h^{\mathcal{O}(1)}, \nabla^{f^*\mathcal{O}(1)})$ .

**2.5. A generalization of do Carmo-Wallach theory.** First of all, we introduce a generalization of Theorem of Takahashi [6] specialized to the case where the target is the projective space.

**Theorem 2.1.** *Let  $f : M \rightarrow Gr_n(\mathbf{C}^{n+1}) = \mathbf{P}^n$  be a full map with constant energy density from a Riemannian manifold  $M$ . Then  $f$  is harmonic if and only if  $\mathbf{C}^{n+1}$  is a subspace of an eigenspace of the Laplacian  $\Delta$  acting on sections of  $f^*\mathcal{O}(1) \rightarrow M$  defined by the induced connection  $\nabla^{f^*\mathcal{O}(1)}$  with  $e(f)/2$  as the eigenvalue, where  $e(f)$  is the energy density of  $f$ .*

Next, we develop a generalization of do Carmo-Wallach theory. Let  $Gr_p(\mathbf{C}^n)$  denote a Grassmannian of  $p$ -planes in  $\mathbf{C}^n$ . Suppose that  $f_1$  and  $f_2 : M \rightarrow Gr_p(\mathbf{C}^n)$  are smooth maps. Then  $f_1$  is said to be *image equivalent* to  $f_2$ , if there exists an isometry  $\psi \in \text{SU}(n)$  of  $Gr_p(\mathbf{C}^n)$  such that  $f_2 = \psi \circ f_1$ .

Let  $G$  be a compact Lie group and  $W$  a unitary representation of  $G$  with an invariant Hermitian inner product  $(\cdot, \cdot)_W$ . The set of Hermitian endomorphisms of  $W$  is denoted by  $\text{H}(W)$ . Then  $G$  naturally acts on  $\text{H}(W)$ . If we equip  $\text{H}(W)$  with an inner product  $(\cdot, \cdot)_H$  such that  $(A, B) = \text{trace } AB$ , for  $A, B \in \text{H}(W)$ , then  $(\cdot, \cdot)_H$  is  $G$ -invariant. We define a Hermitian endomorphism  $H(u, v)$  for  $u, v \in W$  as:

$$H(u, v) := \frac{1}{2} \{u \otimes (\cdot, v)_W + v \otimes (\cdot, u)_W\}.$$

If  $U$  and  $V$  are (complex) subspaces of  $W$ , we denote by  $H(U, V)$  a real subspace of  $\text{H}(W)$  spanned by  $H(u, v)$  where  $u \in U$  and  $v \in V$ . In a similar fashion,  $GH(U, V)$  denotes the subspace of  $\text{H}(W)$  spanned by  $gH(u, v)$ , where  $g \in G$ , and so  $GH(U, V)$  is a  $G$ -submodule of  $\text{H}(W)$ .

Let  $G/K$  be a compact reductive Riemannian homogeneous space with  $K$ -invariant decomposition  $\mathfrak{g} = \mathfrak{k} \oplus \mathfrak{m}$ , where  $\mathfrak{g}$  and  $\mathfrak{k}$  are the Lie algebras of  $G$  and  $K$ , respectively. On the principal fiber bundle  $G \rightarrow G/K$  with the fiber  $K$ , the canonical connection is defined as taking the horizontal subspace as  $L_g\mathfrak{m}$ , where  $g \in G$  and  $L_g$  means the left translation by  $g$ .

For an irreducible unitary  $K$ -module  $V_0$ , the vector bundle  $V = G \times_K V_0$  is called an *irreducible homogeneous vector bundle*. Then the canonical connection induces the covariant derivative on  $V \rightarrow G/K$  which is also said the canonical connection denoted by  $\nabla^0$ .

Let  $W \subset \Gamma(V)$  be a  $G$ -invariant subspace of  $\Gamma(V)$  with the evaluation map  $ev : \underline{W} \rightarrow V$  and a  $G$ -invariant Hermitian inner product  $(\cdot, \cdot)_W$ . Then we can realize  $V_0$  as a subspace of  $W$  by Frobenius reciprocity and the adjoint map  $ev^* : V \rightarrow \underline{W}$  of  $ev$ .

Denote by  $U_0$  the orthogonal complement of  $V_0$  in  $W$ . Then, the map  $f_0 : M \rightarrow Gr_p(W)$  is defined as:

$$f_0([g]) = gU_0 \subset W, \quad \text{for all } [g] \in G/K, \quad g \in G,$$

which is called the *standard map*. It is obviously an  $G$ -equivariant map.

In the sequel,  $Q \rightarrow Gr_p(\mathbf{C}^n)$  denotes the universal quotient bundle [1, p.292]. A Hermitian

inner product on  $\mathbf{C}^n$  induces the Hermitian metric  $h_Q$  on  $Q \rightarrow Gr_p(\mathbf{C}^n)$ . Since  $Q \rightarrow Gr_p(\mathbf{C}^n)$  is a holomorphic vector bundle, we have the connection  $\nabla^Q$  compatible with  $h_Q$  and holomorphic vector bundle structure as the Hermitian connection.

Combining Theorem 5.12 with Theorem 5.30 in [6], we obtain

**Theorem 2.2.** *Let  $G/K$  be a compact reductive Riemannian homogeneous space with  $K$ -invariant decomposition  $\mathfrak{g} = \mathfrak{k} \oplus \mathfrak{m}$ . Fix a rank  $q$  irreducible homogeneous vector bundle  $(V = G \times_K V_0, h, \nabla^0)$  with an invariant metric  $h$  and the canonical connection  $\nabla^0$ . Since  $\nabla^0$  is  $G$ -invariant,  $W$  can be regarded as  $\mathfrak{g}$ -representation  $\varrho : \mathfrak{g} \rightarrow \text{End}(W)$ . We can realize  $V_0$  as a subspace of  $W$  by Frobenius reciprocity and  $(\cdot, \cdot)_W$ .*

*If  $f : G/K \rightarrow (Gr_p(\mathbf{C}^n), (\cdot, \cdot))$  ( $n = p + q$ ) is a full harmonic map with the gauge condition for  $(V, h, \nabla^0)$  and we fix a bundle isomorphism between  $(V, h, \nabla^0)$  and  $(f^*Q, f^*h_Q, \nabla^{f^*Q})$ , then there exist an eigenspace  $W \subset \Gamma(V)$  of the Laplacian with the  $L^2$  Hermitian inner product  $(\cdot, \cdot)_W$ , a unique linear injection  $\iota : \mathbf{C}^n \rightarrow W$  and a positive semi-definite Hermitian endomorphism  $T$  on  $W$  such that*

(a)  $T$  satisfies

$$(2.1) \quad (T^2 - Id_W, GH(V_0, V_0))_H = 0, \quad (T^2, GH(\varrho(\mathfrak{m})V_0, V_0))_H = 0,$$

(b)  $\iota(\mathbf{C}^n) = \text{Ker } T^\perp$  and  $(\iota^*T\iota, \iota^*T\iota) = \iota^*(\cdot, \cdot)_W$ .

(c)  $f : G/K \rightarrow (Gr_p(\mathbf{C}^n), (\cdot, \cdot))$  is written as :

$$(2.2) \quad f([g]) = (\iota^*T\iota)^{-1}(f_0([g]) \cap \text{Ker } T^\perp),$$

which is called the map induced by a triple  $(V, \mathbf{C}^n, \iota(\iota^*T\iota))$ .

Conversely, if a positive semi-definite Hermitian endomorphism  $T$  on  $W$  satisfies condition (a) and  $\mathbf{C}^n := (\text{Ker } T)^\perp$  globally generates  $V \rightarrow M$ , then the map defined by (2.2) is a full harmonic map into  $(Gr_p(\mathbf{C}^n), \iota^*(\cdot, \cdot)_W)$  with the gauge condition for  $(V, h, \nabla^0)$ , where  $\iota : \mathbf{C}^n \rightarrow W$  is the inclusion.

Let  $f_i : M \rightarrow (Gr_p(\mathbf{C}^n), (\cdot, \cdot)_W)$  be the maps induced by those triples  $(V, \mathbf{C}^n, \iota(\iota^*T_i\iota))$  such that  $\iota(\mathbf{C}^n)^\perp = \text{Ker } T_1 = \text{Ker } T_2$ , where  $\iota : \mathbf{C}^n \rightarrow W$  is the inclusion. Then,  $f_1$  and  $f_2$  are gauge equivalent if and only if  $T_1 = T_2$ .

**REMARK.** In the above Theorem, we adopt *gauge equivalence* of maps to classify harmonic maps. When the target is the projective space, the gauge equivalence can be replaced by *image equivalence* [6] and we do not need the definition of gauge equivalence in this article.

**REMARK.** If  $evev^* = Id_V$  or equivalently, the standard map is a full harmonic map with the gauge condition for  $(V, h, \nabla^0)$ , then we can show that  $\text{trace } T^2 = \text{trace } Id_W$  [6]. Hence  $C = T^2 - Id_W$  is orthogonal to  $Id_W$  from the definition of the inner product on  $H(W)$ .

### 3. 3-sphere

Let  $S^3$  be the 3-dimensional sphere with the standard metric. The corresponding symmetric pair is denoted by  $(\text{SU}_+(2) \times \text{SU}_-(2), \Delta)$ , which is abbreviated to  $(\text{SU}_+ \times \text{SU}_-, \Delta)$ , where  $\Delta$  is a diagonal subgroup of  $\text{SU}_+(2) \times \text{SU}_-(2)$ . When we denote by  $S^k\mathbf{C}^2$  the  $k$ -th symmetric

power of the standard representation  $\mathbf{C}^2$  of  $SU(2)$ ,  $S^k \mathbf{C}^2$  inherits an invariant Hermitian inner product  $h$  and a real or quaternionic structure denoted by  $\tau = j^k$ , where  $j$  is a quaternionic structure on  $\mathbf{C}^2$ . The irreducible representation of  $SU_{\pm}(2)$  and  $\Delta$  are denoted by  $S_{\pm}^k$  and  $S_{\Delta}^k$ , respectively and the induced invariant structures are indicated by adding  $\pm$  and  $\Delta$  to the symbols, for instance,  $\tau_{\pm}$  and  $h_{\Delta}$ .

By Clebsch-Gordan,  $S_+^{k_1} \otimes S_-^{k_2}$  irreducibly decomposes as  $\Delta$ -module:

$$S_+^{k_1} \otimes S_-^{k_2} = S_{\Delta}^{k_1+k_2} \oplus S_{\Delta}^{k_1+k_2-2} \oplus \cdots \oplus S_{\Delta}^{|k_1-k_2|-2} \oplus S_{\Delta}^{|k_1-k_2|}.$$

Hence  $S_+^{k_1} \otimes S_-^{k_2}$  is a class one representation of  $(SU_+ \times SU_-, \Delta)$  if and only if  $k_1 = k_2$ . Thus  $\mathcal{H}^k := S_+^k \otimes S_-^k$  is a class one representation of  $(SU_+ \times SU_-, \Delta)$ :

$$\mathcal{H}^k = S_+^k \otimes S_-^k = S_{\Delta}^{2k} \oplus S_{\Delta}^{2k-2} \oplus \cdots \oplus S_{\Delta}^2 \oplus S_{\Delta}^0.$$

Since every class one representation appears in  $C^{\infty}(S^3)$  with multiplicity one, we can conclude that

$$C^{\infty}(S^3) = \sum_{k=0}^{\infty} S_+^k \otimes S_-^k = \sum_{k=0}^{\infty} \mathcal{H}^k.$$

When we denote by  $V \rightarrow S^3$  a trivial bundle  $(SU_+ \times SU_-) \times_{\Delta} S_{\Delta}^0$ , the evaluation map  $ev : \mathcal{H}^k \rightarrow V$  is written as  $ev_{[g]}(w) = ([g], \pi_0(gw))$ , where  $g \in SU_+ \times SU_-$ ,  $w \in \mathcal{H}^k$  and  $\pi_0 : \mathcal{H}^k \rightarrow S_{\Delta}^0$  is the orthogonal projection. We can see that  $\mathcal{H}^k$  is the eigenspace of the Laplacian with eigenvalue  $k(k+2)$  and the  $L^2$  Hermitian inner product  $(\cdot, \cdot)_k$  on  $\mathcal{H}^k$  is an  $SU_+ \times SU_-$ -invariant inner product. Since  $\mathcal{H}^k$  is irreducible as an  $SU_+ \times SU_-$ -module, we can suppose that  $(\cdot, \cdot)_k$  is induced by an invariant inner product  $h_{\pm}$  on  $S_{\pm}^k$  and the restriction of  $(\cdot, \cdot)_k$  to  $S_{\Delta}^0$  is  $h_{\Delta}$ . Thus  $ev : \mathcal{H}^k \rightarrow V$  satisfies  $ev ev^* = Id_V$ .

By the real or quaternionic structure  $\tau = j^k$  on  $S^k \mathbf{C}^2$ ,  $w \mapsto h(\cdot, \tau(w))$  gives  $S^k \mathbf{C}^2 \cong S^k \mathbf{C}^{2*}$ . Thus we can induce the real structure  $\sigma$  on  $\mathcal{H}^k$  and regard  $\text{End } \mathcal{H}^k$  with  $\mathcal{H}^k \otimes \mathcal{H}^k$ . From Clebsch-Gordan,  $\text{End } \mathcal{H}^k$  has an  $SU_+ \times SU_-$ -irreducible decomposition:

$$\begin{aligned} \text{End } \mathcal{H}^k &= S_+^k \otimes S_-^k \otimes S_+^k \otimes S_-^k \\ &\cong (S_+^{2k} \oplus S_+^{2k-2} \oplus \cdots \oplus S_+^2 \oplus S_+^0) \otimes (S_-^{2k} \oplus S_-^{2k-2} \oplus \cdots \oplus S_-^2 \oplus S_-^0) \\ &= \bigoplus_{i,j=0}^k S_+^{2k-2i} \otimes S_-^{2k-2j} = \bigoplus_{i,j=0}^k S_+^{2i} \otimes S_-^{2j}. \end{aligned}$$

When  $S^2 \mathcal{H}^k$  (resp.  $\wedge^2 \mathcal{H}^k$ ) denotes the space of symmetric (resp. skew-symmetric) product of degree 2 on  $\mathcal{H}^k$ ,  $\text{End } \mathcal{H}^k$  has another decomposition:  $\text{End } \mathcal{H}^k = S^2 \mathcal{H}^k \oplus \wedge^2 \mathcal{H}^k$ . Since

$$S^2(S^k \mathbf{C}^2) = \bigoplus_{i=0}^{\lfloor \frac{k}{2} \rfloor} S^{2k-4i}, \quad \wedge^2(S^k \mathbf{C}^2) = \begin{cases} \bigoplus_{i=0}^{\lfloor \frac{k}{2} \rfloor - 1} S^{2k-4i-2}, & k : \text{even} \\ \bigoplus_{i=0}^{\lfloor \frac{k}{2} \rfloor} S^{2k-4i-2}, & k : \text{odd} \end{cases}$$

where  $\lfloor \frac{k}{2} \rfloor$  is the greatest integer which does not exceed  $\frac{k}{2}$ , we get

$$S^2 \mathcal{H}^k = \bigoplus_{l,m=0, |l-m| \equiv 0 \pmod{2}}^k S_+^{2l} \otimes S_-^{2m},$$

$$(3.1) \quad \wedge^2 \mathcal{H}^k = \bigoplus_{l,m=0, |l-m| \equiv 1 \pmod{2}}^k S_+^{2l} \otimes S_-^{2m}.$$

The corresponding Lie algebra homomorphisms into  $\mathcal{H}^k$  (resp.  $S^2 \mathcal{H}^k$  and  $\wedge^2 \mathcal{H}^k$ ) are denoted by  $\varrho_{\mathcal{H}^k}$ , (resp.  $\varrho_{S^2 \mathcal{H}^k}$  and  $\varrho_{\wedge^2 \mathcal{H}^k}$ ).

#### 4. Moduli spaces

We can specialize Theorem 2.2 to the case where the domain manifold is the 3-sphere  $SU_+ \times SU_- / \Delta$  and  $f : S^3 \rightarrow \mathbf{P}^n = \mathbf{P}(\mathbf{C}^{n+1})$  is a harmonic totally real map with constant energy density. The canonical complement of the pair  $(SU_+ \times SU_-, \Delta)$  is denoted by  $\mathfrak{m}$  [7].

Since the Kähler form on  $\mathbf{P}^n$  is the curvature form of  $\mathcal{O}(1) \rightarrow \mathbf{P}^n$  and the pull-back of the Kähler form vanishes from  $f$  being a totally real map, the pull-back bundle of  $\mathcal{O}(1) \rightarrow \mathbf{P}^n$  is a flat bundle on  $S^3$ . It also has a Hermitian metric compatible with the connection. Since  $S^3$  is simply-connected,  $f^* \mathcal{O}(1) \rightarrow S^3$  is a trivial bundle with a product connection and the space of sections of  $f^* \mathcal{O}(1)$  is identified with  $C^\infty(S^3)$ . Thus  $f$  satisfies the gauge condition for  $(V \rightarrow S^3, h_\Delta, \nabla^0)$ , where  $h_\Delta$  is now recognized as the fiber metric on  $V \rightarrow S^3$  and  $f^* \mathcal{O}(1) \rightarrow S^3$  has a preferred trivialization. Notice that a trivial line bundle  $V \rightarrow S^3$  is regarded as an irreducible homogeneous vector bundle and the product connection as the canonical one  $\nabla^0$ . Since the energy density is constant, Theorem 2.1 yields that  $\mathbf{C}^{n+1}$  is the eigenspace of the Laplacian.

**DEFINITION 4.1.** Let  $f : S^3 \rightarrow \mathbf{P}^n = \mathbf{P}(\mathbf{C}^{n+1})$  be a harmonic totally real map with constant energy density. If  $\mathbf{C}^{n+1}$  is a subspace of the eigenspace with  $k(k+2)$  as the eigenvalue of the Laplacian, then  $f$  is said to be of *degree*  $k$ .

Let  $\mathcal{H}^k$  be a class one representation of  $(SU_+ \times SU_-, \Delta)$ . We abbreviate  $S_\Delta^0 \subset \mathcal{H}^k$  to  $V_0$ . From the identification  $S^k \mathbf{C}^2 \cong S^k \mathbf{C}^{2*}$  by  $w \mapsto h(\cdot, \tau(w))$ ,  $\mathcal{H}^k$  can be regarded as  $\text{Hom}(S_-^k, S_+^k) \cong S_+^k \otimes S_-^{k*}$ . Since  $\text{Hom}(S_-^k, S_+^k)$  is  $\text{End}(S_\Delta^k, S_\Delta^k)$  as  $\Delta$ -module,  $V_0$  is identified with the subspace of  $\mathcal{H}^k$  generated by  $Id_{S_\Delta^k}$ . When we denote by  $v_0 \in \mathcal{H}^k$  the basis of  $V_0$  corresponding to  $Id_{S_\Delta^k}$  and by  $w_k^\pm, w_{k-2}^\pm, \dots, w_{-k+2}^\pm, w_{-k}^\pm$  a unitary basis of  $S_\pm^k$  with weight  $k-2i$  ( $i = 0, 1, \dots, k$ ), it follows from the definition of  $v_0 \in \mathcal{H}^k = S_+^k \otimes S_-^{k*}$  that

$$v_0 = \sum_{i=0}^k w_{k-2i}^+ \otimes w_{k-2i}^{-*},$$

where  $w_k^{-*}, w_{k-2}^{-*}, \dots, w_{-k+2}^{-*}, w_{-k}^{-*}$  is the dual basis of  $S_-^{k*}$ . From the identification, we can see that

$$w_{k-2i} \mapsto (-1)^i w_{-k+2i}^*, \quad \text{or} \quad w_{k-2i}^* \mapsto (-1)^{k-i} w_{-k+2i}.$$

Thus, when  $\mathcal{H}^k$  is considered as  $S_+^k \otimes S_-^{k*}$ ,  $v_0$  is written as:

$$v_0 = \sum_{i=0}^k (-1)^{k-i} w_{k-2i}^+ \otimes w_{-k+2i}^-.$$

We consider  $\text{H}(\mathcal{H}^k)$  the set of Hermitian endomorphisms of  $\mathcal{H}^k$ , when applying Theorem 2.2. Then, we need to specify  $GH(V_0, V_0)$  and  $GH(\mathfrak{m}V_0, V_0)$  in  $\text{H}(\mathcal{H}^k)$ . To do this, we

complexify  $GH(V_0, V_0)$  and  $GH(mV_0, V_0)$  and specify them in  $\text{End } \mathcal{H}^k$ . The complexified spaces are denoted by the same symbols.

Since  $V_0$  is a trivial representation and  $mV_0 = S_\Delta^2$ ,  $H(V_0, V_0)$  is also trivial and  $H(mV_0, V_0)$  consists of vectors of weight  $\pm 2$  as  $\Delta$ -modules. It follows from Frobenius reciprocity and Clebsch-Gordan that

$$(4.1) \quad \begin{aligned} & GH(V_0, V_0), GH(mV_0, V_0) \\ & \subset \bigoplus_{l,m=0,|l-m|=0}^k S_+^{2l} \otimes S_-^{2m} \oplus \bigoplus_{l,m=0,|l-m|=2}^k S_+^{2l} \otimes S_-^{2m} \\ & = \bigoplus_{l=0}^k S_+^{2l} \otimes S_-^{2l} \oplus \bigoplus_{l=1}^k S_+^{2l} \otimes S_-^{2l-2} \oplus S_+^{2l-2} \otimes S_-^{2l}. \end{aligned}$$

**Proposition 4.2.** *The standard map  $f_0 : S^3 \rightarrow \mathbf{P}(\mathcal{H}^{k*})$  induced by a pair  $(S^3 \times V_0, \mathcal{H}^k)$  is a harmonic totally real map of degree  $k$  with constant energy density.*

*Proof.* Since the standard map is  $SU_+ \times SU_-$ -invariant,  $f_0$  has constant energy density. In Theorem 2.2, the standard map  $f_0$  corresponds to  $Id_W$ . For  $W = \mathcal{H}^k$ , (4.1) assures that  $Id_W$  satisfies (2.1). Theorem 2.2 yields that it is a harmonic map and the curvature of the pull-back connection is flat. Thus  $f_0$  is a totally real map. Since  $\mathcal{H}^k$  is the eigenspace with eigenvalue  $k(k+2)$ ,  $f_0$  is of degree  $k$ .  $\square$

We now see the decomposition  $\text{End } \mathcal{H}^k = S^2\mathcal{H}^k \oplus \wedge^2\mathcal{H}^k$  in detail. Let  $\mathcal{H}_{\mathbf{R}}^k$  denote the real subspace of  $\mathcal{H}^k$  invariant by  $\sigma = \tau_+ \otimes \tau_-$  on  $\mathcal{H}^k$ . Then the real Grassmannian of hyperplanes in  $\mathcal{H}_{\mathbf{R}}^k$  is a totally geodesic and totally real submanifold  $i : \mathbf{RP}(\mathcal{H}_{\mathbf{R}}^{k*}) \rightarrow \mathbf{P}(\mathcal{H}^{k*})$ .

If  $C \in S^2\mathcal{H}^k$  (resp.  $C \in \wedge^2\mathcal{H}^k$ ) is a Hermitian endomorphism of  $\mathcal{H}^k$ , then, by the real structure  $\sigma$  on  $\mathcal{H}^k$ , we have that  $\sigma C \sigma = C$  (resp.  $\sigma C \sigma = -C$ ). For any  $w \in \mathcal{H}_{\mathbf{R}}^k$ , when  $C \in H(\mathcal{H}^k) \cap S^2\mathcal{H}^k$ ,

$$(4.2) \quad \sigma(Cw) = \sigma(\sigma C \sigma \sigma(w)) = Cw,$$

and when  $C \in H(\mathcal{H}^k) \cap \wedge^2\mathcal{H}^k$ ,

$$(4.3) \quad \sigma(Cw) = \sigma(-\sigma C \sigma \sigma(w)) = -Cw.$$

Suppose that  $C \in H(\mathcal{H}^k) \cap S^2\mathcal{H}^k$ . For (4.2),  $C$  preserves  $\mathcal{H}_{\mathbf{R}}^k$  and defines a symmetric endomorphism on  $\mathcal{H}_{\mathbf{R}}^k$ . Then Toth-D'ambra classification [8] yields that  $C$  corresponds to a full harmonic map with constant energy density of  $S^3$  into the sphere. Since they adopt an (image) equivalence relation by the orthogonal group, the target can be replaced by the real projective space  $\mathbf{RP}(\mathcal{H}_{\mathbf{R}}^{k*})$ .

**Proposition 4.3.** *We have that*

$$\begin{aligned} & GH(V_0, V_0) \oplus GH(mV_0, V_0) \\ & = \bigoplus_{l=0}^k S_+^{2l} \otimes S_-^{2l} \oplus \bigoplus_{l=1}^k S_+^{2l} \otimes S_-^{2l-2} \oplus S_+^{2l-2} \otimes S_-^{2l}. \end{aligned}$$

Proof. It follows from do Carmo-Wallach [2] and Toth-D'ambra [8] that

$$GH(V_0, V_0) \cap S^2\mathcal{H}^k = \bigoplus_{l=0}^k S_+^{2l} \otimes S_-^{2l}.$$

We use induction on  $k$  to show the result. Since  $\mathcal{H}^1 = S_+^1 \otimes S_-^1$ ,

$$\wedge^2\mathcal{H}^1 = S_+^2 \oplus S_-^2.$$

As  $\mathfrak{m}V_0 = S_\Delta^2$ , the definition of  $GH(\mathfrak{m}V_0, V_0)$  yields the result.

From (3.1),  $\wedge^2\mathcal{H}^k$  is decomposed as  $SU_+ \times SU_-$ -module:

$$\wedge^2\mathcal{H}^k = \bigoplus_{j=0}^{\lfloor \frac{k}{2} \rfloor} (S_+^{2k} \otimes S_-^{2k-4j-2} \oplus S_+^{2k-4j-2} \otimes S_-^{2k}) \oplus \wedge^2\mathcal{H}^{k-1}.$$

We would like to claim that

$$\begin{aligned} & GH(\mathfrak{m}V_0, V_0) \cap \wedge^2\mathcal{H}^k \\ &= S_+^{2k} \otimes S_-^{2k-2} \oplus S_+^{2k-2} \otimes S_-^{2k} \oplus (GH(\mathfrak{m}V_0, V_0) \cap \wedge^2\mathcal{H}^{k-1}). \end{aligned}$$

Since, for  $Z, W \in \mathfrak{sl}(2, \mathbf{C})$  and a non-negative integer  $p$ ,

$$\varrho_{\mathcal{H}^k}(Z, W)^p v_0 = \sum_{i=0}^k (-1)^{k-i} \sum_{r=0}^p \binom{p}{r} (\varrho(Z)^{p-r} w_{k-2i}^+) \otimes (\varrho(W)^r w_{-k+2i}^-),$$

we get

$$\begin{aligned} (4.4) \quad & \varrho_{\mathcal{H}^k}(Z, -Z)^{k-1} v_0 \\ &= \sum_{i=0}^{k-1} (-1)^{k-i} \sum_{r=0}^{k-1} \binom{k-1}{r} (\varrho(Z)^{k-1-r} w_{k-2i}^+) \otimes (\varrho(-Z)^r w_{-k+2i}^-). \end{aligned}$$

We pick up an element  $Z \in \mathfrak{m}^C \subset \mathfrak{sl}(2, \mathbf{C})$ , where  $\mathfrak{m}^C$  denotes the complexified space of  $\mathfrak{m}$ , in such a way that

$$(4.5) \quad \varrho(Z)w_{k-2i} = \sqrt{(k-i)(i+1)}w_{k-2i-2},$$

and put  $v_1 = \varrho_{\mathcal{H}^k}(Z, -Z)v_0$ . Since  $v_0$  is  $\sigma$  invariant by definition and  $\varrho_{\mathcal{H}^k}$  commutes with  $\sigma$ ,  $v_1$  is also  $\sigma$  invariant. This yields that  $v_0 \wedge v_1 \in GH(\mathfrak{m}V_0, V_0) \cap \wedge^2\mathcal{H}^k$ .

It follows from (4.5) that

$$(4.6) \quad \varrho(Z)^q w_{k-2i} = \sqrt{\frac{(k-i)!}{(k-i-q)!} \frac{(i+q)!}{i!}} w_{k-2(i+q)},$$

and

$$(4.7) \quad \varrho(Z)^q w_{-k+2i} = \sqrt{\frac{(k-i+q)!}{(k-i)!} \frac{i!}{(i-q)!}} w_{-k+2(i-q)}.$$

Since  $w_{k-2i}$  and  $w_{-k+2i} \in S^k\mathbf{C}^2$ , we see from (4.6) and (4.7) that

$$\varrho(Z)^q w_{k-2i} = 0 \iff k-2i-2q < -k \iff q > k-i,$$

$$\varrho(Z)^q w_{-k+2i} = 0 \iff -k + 2i - 2q < -k \iff q > i.$$

Consequently,

$$\varrho(Z)^{k-1-r} w_{k-2i} = 0 \iff k-1-r > k-i \iff r < i-1.$$

Thus only the terms in the range  $i-1 \leq r \leq i$  in (4.4) remains:

$$(4.8) \quad \begin{aligned} & \varrho_{\mathcal{H}^k}(Z, -Z)^{k-1} v_0 \\ &= \sum_{i=1}^k (-1)^{k-i} \left\{ \binom{k-1}{i-1} (\varrho(Z)^{k-i} w_{k-2i}^+) \otimes (\varrho(-Z)^{i-1} w_{-k+2i}^-) \right\} \\ &+ \sum_{i=0}^{k-1} (-1)^{k-i} \left\{ \binom{k-1}{i} (\varrho(Z)^{k-i-1} w_{k-2i}^+) \otimes (\varrho(-Z)^i w_{-k+2i}^-) \right\} \\ &= \sum_{i=1}^k (-1)^{k-1} \left\{ \binom{k-1}{i-1} (\varrho(Z)^{k-i} w_{k-2i}^+) \otimes (\varrho(Z)^{i-1} w_{-k+2i}^-) \right\} \\ &+ \sum_{i=0}^{k-1} (-1)^k \left\{ \binom{k-1}{i} (\varrho(Z)^{k-i-1} w_{k-2i}^+) \otimes (\varrho(Z)^i w_{-k+2i}^-) \right\}. \end{aligned}$$

It follows from (4.6) and (4.7) that

$$\begin{aligned} \varrho(Z)^{k-i-1} w_{k-2i}^+ &= \sqrt{\frac{(k-i)!(k-1)!}{i!}} w_{-k+2}^+, \\ \varrho(Z)^{k-i} w_{k-2i}^+ &= \sqrt{\frac{(k-i)!k!}{i!}} w_{-k}^+, \\ \varrho(Z)^{i-1} w_{-k+2i}^- &= \sqrt{\frac{(k-1)!i!}{(k-i)!}} w_{-k+2}^-, \\ \varrho(Z)^i w_{-k+2i}^- &= \sqrt{\frac{k!i!}{(k-i)!}} w_{-k}^-. \end{aligned}$$

Hence (4.8) reduces to:

$$(4.9) \quad \begin{aligned} & \varrho_{\mathcal{H}^k}(Z, -Z)^{k-1} v_0 \\ &= (-1)^{k-1} \sqrt{k}(k-1)! \left\{ \sum_{i=1}^k \binom{k-1}{i-1} \right\} w_{-k}^+ \otimes w_{-k+2}^- \\ &+ (-1)^k \sqrt{k}(k-1)! \left\{ \sum_{i=0}^{k-1} \binom{k-1}{i} \right\} w_{-k+2}^+ \otimes w_{-k}^- \\ &= (-1)^{k-1} \sqrt{k}(k-1)! 2^{k-1} (w_{-k}^+ \otimes w_{-k+2}^- - w_{-k+2}^+ \otimes w_{-k}^-). \end{aligned}$$

It follows from  $\varrho(Z)w_{-k+2} = \sqrt{k}w_{-k}$  that

$$(4.10) \quad \begin{aligned} \varrho_{\mathcal{H}^k}(Z, -Z)^k v_0 &= (-1)^{k-1} k! 2^{k-1} (-w_{-k}^+ \otimes w_{-k}^- - w_{-k}^+ \otimes w_{-k}^-) \\ &= (-1)^k k! 2^k w_{-k}^+ \otimes w_{-k}^- \end{aligned}$$

and  $\varrho_{\mathcal{H}^k}(Z, -Z)^p v_0 = 0$ , when  $p > k$ . Then we have that

$$\begin{aligned} & \varrho_{\wedge^2 \mathcal{H}^k}(Z, -Z)^{2k-2} (v_0 \wedge v_1) \\ &= 4(k-1) \binom{2k-1}{k} \varrho_{\mathcal{H}^k}(Z, -Z)^{k-1} v_0 \wedge \varrho_{\mathcal{H}^k}(Z, -Z)^k v_0. \end{aligned}$$

From (4.9) and (4.10), considering the weights, we can conclude that

$$\varrho_{\wedge^2 \mathcal{H}^k}(Z, -Z)^{2k-2} (v_0 \wedge v_1) \in S_+^{2k} \otimes S_-^{2k-2} \oplus S_+^{2k-2} \otimes S_-^{2k},$$

and  $S_+^{2k} \otimes S_-^{2k-2} \oplus S_+^{2k-2} \otimes S_-^{2k}$  is a subset of  $GH(mV_0, V_0)$ . Combining this with (4.1), we obtain the result.  $\square$

Theorem 2.2 with Propositions 4.2 and 4.3 yields the main result. To state the main theorem, we adopt the convention that  $S_+^{2k} \otimes S_-^{2l}$  stands for the real vector space invariant by the real structure  $\tau_+ \otimes \tau_-$ . For  $T \in \mathbf{H}(\mathcal{H}^k)$ , we write  $T > 0$  to indicate that  $T$  is positive definite.

**Theorem 4.4.** *If  $f : S^3 \rightarrow \mathbf{P}(\mathbf{C}^{n^*})$  is a full harmonic totally real map of degree  $k$  with a constant energy density, then  $n \leq (k+1)^2$  and  $\mathbf{C}^n$  is considered as a subspace of  $\mathcal{H}^k$ .*

*Let  $\mathcal{M}_k$  be the moduli space of full harmonic totally real maps of degree  $k$  with constant energy density of  $S^3$  into  $\mathbf{P}(\mathcal{H}^{k^*})$  modulo image equivalence of maps. Then  $\mathcal{M}_k$  is identified with a subset of  $\bigoplus_{l,m=0, |l-m| \geq 2}^k S_+^{2l} \otimes S_-^{2m}$ :*

$$\mathcal{M}_k = \left\{ C \in \bigoplus_{l,m=0, |l-m| \geq 2}^k S_+^{2l} \otimes S_-^{2m} \mid Id_{\mathcal{H}^k} + C > 0 \right\},$$

where  $\bigoplus_{l,m=0, |l-m| \geq 2}^k S_+^{2l} \otimes S_-^{2m}$  is regarded as a subspace of  $\mathbf{H}(\mathcal{H}^k)$ .

*Let  $\overline{\mathcal{M}}_k$  be the closure of the moduli  $\mathcal{M}_k$  by topology induced from the inner product. Every boundary point of  $\overline{\mathcal{M}}_k$  distinguishes a subspace  $\mathbf{C}^n$  of  $\mathcal{H}^k$  and describes one of those maps into  $\mathbf{P}(\mathbf{C}^{n^*})$  which can be regarded as a totally geodesic submanifold of  $\mathbf{P}(\mathcal{H}^{k^*})$ . The Hermitian inner product on  $\mathcal{H}^k$  determines the orthogonal decomposition of  $\mathcal{H}^k : \mathcal{H}^k = \mathbf{C}^n \oplus \mathbf{C}^{n^\perp}$ . Then the totally geodesic submanifold  $\mathbf{P}(\mathbf{C}^{n^*})$  can be obtained as the common zero set of sections of  $\mathcal{O}(1) \rightarrow \mathbf{P}(\mathcal{H}^{k^*})$  which belongs to  $\mathbf{C}^{n^\perp}$ .*

*Finally,  $C \in \overline{\mathcal{M}}_k$  corresponds to  $(Id_{\mathcal{H}^k} + C)^{-\frac{1}{2}} f_0$ , under the convention that the inverse of  $Id_{\mathcal{H}^k} + C$  is taken on  $\text{Ker} (Id_{\mathcal{H}^k} + C)^\perp$ .*

**Corollary 4.5.** *Let  $f : S^3 \rightarrow \mathbf{P}(\mathbf{C}^{n^*})$  be an  $SU_+ \times SU_-$ -equivariant full harmonic totally real map. Then  $f$  is the standard map up to image equivalence.*

*Proof.* If  $f$  is of degree  $k$ , Theorem 4.4 implies that  $f$  corresponds to  $C \in \overline{\mathcal{M}}_k$ . Since  $f$  is  $SU_+ \times SU_-$ -equivariant,  $C$  is also an  $SU_+ \times SU_-$ -equivariant linear endomorphism on  $\mathcal{H}^k$ . Schur's lemma yields that  $C$  is proportional to the identity. However,  $C$  is orthogonal to the identity (see the remark after Theorem 2.2). We thus deduce that  $C = 0$ . Then the result follows from Proposition 4.2.  $\square$

In a similar vein, we can characterize  $SU_\pm$ -equivariant harmonic totally real maps, a few examples of which are given in [3]:

**Corollary 4.6.** *A full harmonic totally real map  $f : S^3 \rightarrow \mathbf{P}(\mathbf{C}^{n^*})$  of degree  $k$  is  $SU_+$  (resp.  $SU_-$ )-equivariant if and only if the Hermitian transform  $C$  corresponding to  $f$  is in  $\bigoplus_{m=2}^k S_+^0 \otimes S_-^{2m}$  (resp.  $\bigoplus_{l=2}^k S_+^{2l} \otimes S_-^0$ ).*

We define the subset  $\mathcal{AM}_k$  of the moduli space  $\mathcal{M}_k$  by:

$$\mathcal{AM}_k = \mathcal{M}_k \cap S^2\mathcal{H}^k.$$

**Theorem 4.7.** *The moduli space of absolutely real full harmonic totally real maps of degree  $k$  with constant energy density of  $S^3$  into  $\mathbf{P}(\mathcal{H}^{k^*})$  is identified with  $\mathcal{AM}_k$ .*

Proof. In [8], Toth-D'ambra constructs the moduli space  $\mathbf{M}_k$  of full harmonic maps from  $S^3$  into the sphere of degree  $k$  with constant energy density:

$$\mathbf{M}_k := \left\{ C \in \bigoplus_{l,m=0,|l-m|=2i,i \geq 1}^k S_+^{2l} \otimes S_-^{2m} \mid Id_{\mathcal{H}^k_{\mathbf{R}}} + C > 0 \right\},$$

where  $\bigoplus_{l,m=0,|l-m|=2i,i \geq 1}^k S_+^{2l} \otimes S_-^{2m}$  is considered as a subset of symmetric endomorphisms on  $\mathcal{H}_{\mathbf{R}}^k$ . When  $\mathcal{H}_{\mathbf{R}}^k$  is complexified,  $C$  defines a Hermitian endomorphism of  $\mathcal{H}^k$  and belongs to  $\mathcal{AM}_k$ .

Suppose that  $C \in \mathcal{AM}_k$ . Since  $C$  preserves  $\mathcal{H}_{\mathbf{R}}^k$  by (4.2), it defines a symmetric endomorphism on  $\mathcal{H}_{\mathbf{R}}^k$ . Thus we can identify  $\mathbf{M}_k$  with  $\mathcal{AM}_k$ .

To see the correspondence of maps according to  $\mathbf{M}_k \cong \mathcal{AM}_k$ , we take a subspace  $U_0^{\mathbf{R}} = U_0 \cap \mathcal{H}_{\mathbf{R}}^k$  to define the standard map  $f_0^{\mathbf{R}}$  of  $S^3$  into  $\mathbf{RP}(\mathcal{H}_{\mathbf{R}}^{k^*})$  as  $f_0^{\mathbf{R}}([g]) = gU_0^{\mathbf{R}}$ , where  $g \in SU_+ \times SU_-$ . Then, by [8],  $C \in \mathbf{M}_k$  corresponds to  $(Id_{\mathcal{H}_{\mathbf{R}}^k} + C)^{-\frac{1}{2}} f_0^{\mathbf{R}}$ . Our identification between  $\mathbf{M}_k$  and  $\mathcal{AM}_k$  yields  $(Id_{\mathcal{H}^k} + C)^{-\frac{1}{2}} f_0 = i \circ (Id_{\mathcal{H}_{\mathbf{R}}^k} + C)^{-\frac{1}{2}} f_0^{\mathbf{R}}$ .

Suppose that  $f$  is an absolutely real full harmonic totally real map with constant energy density. By image equivalence relation,  $f$  may be supposed to be a map into  $\mathbf{RP}(\mathcal{H}_{\mathbf{R}}^{k^*})$ . From Theorem 4.4 and our identification, there exists  $C \in \mathbf{M}_k$  such that  $f = i \circ (Id_{\mathcal{H}_{\mathbf{R}}^k} + C)^{-\frac{1}{2}} f_0^{\mathbf{R}}$ .  $\square$

EXAMPLE. Let  $\mathcal{M}_2$  be the moduli space of full harmonic totally real maps of degree 2 with constant energy density of  $S^3$  into  $\mathbf{P}(\mathcal{H}^{2^*})$  modulo image equivalence:

$$\mathcal{M}_2 = \left\{ C \in S_+^4 \otimes S_-^0 \oplus S_+^0 \otimes S_-^4 \mid Id_{\mathcal{H}^2} + C > 0 \right\}.$$

From Theorem 4.7, all maps are absolutely real and from Corollary 4.6, those are  $SU_+$  or  $SU_-$ -equivariant ones.

Li obtains an isometric minimal totally real immersion of  $S^3$  into  $\mathbf{P}^{11}$  which is not absolutely real [5]. This immersion is of degree 3. We also give such an example.

EXAMPLE. Let  $\mathcal{M}_3$  be the moduli space of those maps of degree 3 of  $S^3$  into  $\mathbf{P}(\mathcal{H}^{3^*})$  modulo image equivalence.

$$\begin{aligned} \mathcal{M}_3 = \{ C \in & S_+^6 \otimes S_-^2 \oplus S_+^2 \otimes S_-^6 \oplus S_+^4 \otimes S_-^0 \oplus S_+^0 \otimes S_-^4 \\ & \oplus S_+^6 \otimes S_-^0 \oplus S_+^0 \otimes S_-^6 \mid Id_{\mathcal{H}^3} + C > 0 \}. \end{aligned}$$

The unitary basis of  $\mathcal{H}^3$  is denoted by  $w_{3-2l}^+ \otimes w_{3-2m}^-$ , ( $l, m = 0, \dots, 3$ ). If  $C = i(w_6^+ - w_{-6}^+) \in S_+^6 \otimes S_-^0$ , then  $C$  satisfies  $\sigma C \sigma = -C$ . From (4.3), we see that  $C \in \mathbf{H}(\mathcal{H}^3)$  and it is written as:

$$C = i \begin{pmatrix} O & O & O & Id_4 \\ O & O & O & O \\ O & O & O & O \\ -Id_4 & O & O & O \end{pmatrix}.$$

Hence  $Id_{\mathcal{H}^3} + tC$  has 1 and  $1 \pm t$  as its eigenvalues and each eigenspace is of dimension 4, which is equivalent to  $S_-^3$  as  $SU_-$ -module. If  $t \in (0, 1]$ , then  $Id_{\mathcal{H}^3} + tC$  induces a full harmonic totally real map with constant energy density, which is not absolutely real. When  $t = 1$ ,  $Id_{\mathcal{H}^3} + C$  has a kernel of dimension 4. By Theorem 4.4, it induces a full map into  $\mathbf{P}(\mathbf{C}^{12*})$ , where  $\mathbf{C}^{12} \subset \mathcal{H}_3$  is the orthogonal complement of  $\text{Ker}(Id_{\mathcal{H}^3} + C)$ . Corollary 4.6 yields that those maps are  $SU_-$ -equivariant.

In a similar way, using  $w_4^+ + w_{-4}^+ \in S_+^4 \otimes S_-^0$ , we obtain a one parameter family  $f_t$  ( $t \in [0, 1]$ ) of harmonic totally real maps with constant energy density, which is absolutely real and  $f_1$  is a full map into  $\mathbf{P}(\mathbf{R}^{8*})$ , where  $\mathbf{R}^8$  is a subspace of  $SU_+ \times SU_-$ -invariant real subspace  $\mathbf{R}^{16}$  of  $\mathcal{H}^3$ . From Corollary 4.6, we can see that  $f_t$  are  $SU_-$ -equivariant.
