## COMPLETIONS AND MAXIMAL QUOTIENT RINGS OVER REGULAR RINGS

Dedicated to Professor Hiroyuki Tachikawa for his 60th birthday

SHIGERU KOBAYASHI

(Received March 3, 1988)

Let  $R$  be a (Von Neumann) regular ring with rank function  $N$ . Then there exists the  $N$ -metric completion  $\bar{R}$  of  $R$  with respect to  $N$ . It is well known that  $\bar{R}$  is a right and left self-injective regular ring. On the other hand, we have always the maximal right quotient ring  $Q_r^{\max}(R)$  of  $R$ , which is a right self-injective regular ring.

In this paper, we are concerned with the connection between the  $N$ -metric completion of  $R$  and the maximal right quotient ring of  $R$ .

In [1, Theorem 23.17], Goodearl has shown that if for any essential right ideal  $I$  of  $R$ ,  $N(I)=1$ , then  $Q_r^{\max}(R)$  is embeded in  $\bar{R}$  as a subring. Under this condition, we shall show that  $\bar{R}$  is isomorphic to the maximal left quotient ring of  $Q_r^{\max}(R)$ .

Furthermore, we shall show the simillar result with the above result to the case that  $N$  is a pseudo-rank function.

### §1. Preliminaries

Throughout of this paper, we assume that all rings are associative with identity element and all modules are unitary.

Let  $R$  be a reuglar ring. A pseudo-rank function on  $R$  is a map  $N: R \rightarrow [0, 1]$  such that

- (1)  $N(1)=1$  and  $N(0)=0$
- (2)  $N(xy) \leq \text{Max} \{N(x), N(y)\}$ , for any  $x, y$  in  $R$
- (3)  $N(e+f)=N(e)+N(f)$ , for each orthogonal idempotent elements  $e, f$  of  $R$ .

A rank function on  $R$  is a pseudo-rank function with additional property

- (4)  $N(x)=0$  implies  $x=0$ .

If  $N$  is a pseudo-rank function on  $R$ , the the rule  $\delta(x, y)=N(x-y)$  defines a pseudo-metric on  $R$ . Clearly,  $\delta$  is metric if and only if  $N$  is a rank function. The completion  $\bar{R}$  of  $R$  with respect to  $\delta$  is a right and left self-injective regular ring which is complete with respect to the  $\bar{N}$ -metric, where  $\bar{N}$  is the unique extension of  $N$  to  $\bar{R}$ .

If  $N$  is a pseudo-rank function, then we denote that  $\ker N = \{x \in R \mid N(x) = 0\}$ .

We set  $P(R)$  is the set of pseudo-rank functions over  $R$ . We say that  $N$  of  $P(R)$  is an extreme point of  $P(R)$  provided that  $N$  can not be expressed as a positive convex combination of two distinct points of  $P(R)$ .

Let  $I$  be a right ideal of  $R$ . Then we denote that  $N(I) = \text{Sup}\{N(x) \mid x \in I\}$ . Finally, if  $A$  and  $B$  are modules, then the notation  $A \subseteq_e B$  means that  $A$  is an essential submodule of  $B$ .

**§2. Completions over regular rings**

In this section, we prove the following main theorem.

**Theorem 1.** *Let  $R$  be a regular ring with rank function  $N$ . If for any essential right ideal  $I$  of  $R$ ,  $N(I) = 1$ , then the completion  $\bar{R}$  of  $R$  with respect to  $N$ -metric is isomorphic to the maximal left quotient ring of the maximal right quotient ring of  $R$ .*

*Proof.* First we shall show that there exists a ring monomorphism  $\psi$  from the maximal right quotient ring  $Q$  of  $R$  to the completion  $\bar{R}$  of  $R$ . This is proved by the same idea of [1, Theorem 21.17], but we shall give a proof for completeness. Since  $\bar{R}$  is right and left-self-injective regular ring,  $\bar{R}$  is a injective right  $R$ -module. Let  $x$  be any element of  $\bar{R}$  and  $I$  is an essential right ideal of  $R$  such that  $xI = 0$ . Then since  $N(I) = 1$ , for any positive number  $\epsilon$ , there exists an idempotent  $e$  of  $I$  such that  $N(e) > 1 - \epsilon$ . Now since  $x = x - xe$ ,  $\bar{N}(x) = \bar{N}(x - xe) \leq \bar{N}(1 - e) = N(1 - e) < \epsilon$ . Thus  $\bar{N}(x) = 0$ . Since  $\bar{N}$  is a rank function,  $x = 0$ . Therefore  $\bar{R}$  is a non-singular right  $R$ -module. Since  $R$  is essential right submodule of  $Q$  and  $\bar{R}$  is an injective right  $R$ -module, the identity map on  $R$  extends to a right  $R$ -module monomorphism  $\psi: Q \rightarrow \bar{R}$ . We claim that  $\psi$  is a ring homomorphism. Given any elements  $x, y$  in  $Q$ , we have  $yJ \subseteq R$  for some essential right ideal  $J$  of  $R$ . Then  $\psi(xy)r = \psi(xyr) = \psi(x)yr = \psi(x)(y)r$  for all  $r$  in  $J$ . Whence  $[\psi(x)\psi(y) - \psi(xy)]J = 0$ . Since  $\bar{R}$  is non-singular right  $R$ -module, we obtain that  $\psi(xy) = \psi(x)\psi(y)$ , so that  $\psi$  is a ring homomorphism. Next we shall show that for any essential left ideal  $K$  of  $Q$ ,  $N_Q(K) = 1$ , where  $N_Q$  is an extension of  $N$ . Let  $K$  be an essential left ideal of  $Q$ . Then by [1, Lemma 9.7], there exist orthogonal idempotents  $e_1, e_2, \dots$ , such that  $\sum_{n=1}^{\infty} \oplus Qe_n \subseteq_e K \subseteq_e Q$ . We set  $J = \bigoplus_{n=1}^{\infty} e_n Q$ . We claim that  $J$  is an essential right ideal of  $Q$ . If  $J \cap eQ = 0$ , then  $J \oplus eQ \subseteq_e Q$ . On the other hand, since  $Q$  is a right self-injective regular ring, there exist orthogonal idempotents  $e'_n, e'$  such that  $e'_n Q = e_n Q, eQ = e'Q$ . We claim that  $\bigoplus_{n=1}^{\infty} Qe_n \cap Qe' = 0$ . Let  $re' = a_1 e_{n_1} + \dots + a_k e_{n_k}$  be an any element of  $\bigoplus_{n=1}^{\infty} Qe_n \cap Qe'$ . Since  $e_n = e'_n e_n, e'_n = e_n e'_n$ , we have that

$e'e_n = e'(e'_n e_n) = 0$ . Now  $re'e_{n_i} = a_i e_{n_i}$ , so  $re' = 0$ , as claimed. Thus  $e' = 0$ , so that  $e = 0$ . This shows that  $\bigoplus_{n=1}^{\infty} e_n Q$  is an essential right ideal in  $Q$ . Therefore by assumption,  $N_Q(J) = 1$ , which is concluded to that  $N_Q(K) = 1$ . In this case, the maximal left quotient ring of  $Q$  is embedded in  $\bar{R}$  as a subring. Now in order to prove this Theorem, it suffices to show that  $\bar{R}$  is a left essential extension of  $Q$ . Let  $x$  be any element of  $\bar{R}$ . Since  $\bar{R}$  is complete, for any positive number  $\varepsilon$ , there exists an element  $x'$  of  $Q$  such that  $\bar{N}(x - x') < \varepsilon/2$ . We put  $x - x' = y$ , where  $y$  is an element of  $\bar{R}$ . With respect to  $y$ , there exists an element  $x_1$  of  $Q$  such that  $\bar{N}(y - x_1) < \varepsilon/2 \cdot 3$ . Put  $y - x_1 = y_1$ . In general, there exist elements  $x_n$  of  $Q$  such that  $\bar{N}(y_{n-1} - x_n) < \varepsilon/2 \cdot 3^n$ . We put  $y_{n-1} - x_n = y_n$ . Now we have that  $\bar{N}(y - \sum_{i=1}^n x_i) < \varepsilon/2 \cdot 3^n$ . Thus  $\sum x_i$  is a Cauchy sequence. Since  $\bar{R}$  is complete,  $\sum_{i=1}^{\infty} x_i = y$ . Furthermore,  $\sum_{i=1}^{\infty} \bar{N}(x_i) < \bar{N}(y) + 2\{\bar{N}(y_1) + \bar{N}(y_2) + \dots\} < \varepsilon/2 + \sum_{n=1}^{\infty} \varepsilon/3^n = \varepsilon/2 + \varepsilon/2 = \varepsilon$ . Let  $I$  be a right ideal generated by  $x', x_1, \dots$ . Since  $\sum \bar{N}(x_i) < \varepsilon$ ,  $\bar{N}(I) < \varepsilon$ . On the other hand, since  $\sum_{i=1}^{\infty} x_i = y \in \bar{R}$ ,  $y$  is in  $\bar{I}$ , where  $\bar{I}$  is the  $N_Q$ -closure of  $I$ . Let  $e$  be an idempotent element of  $Q$  such that  $I \subseteq_e (1-e)Q$ , then  $eI = 0$ . And since  $I \oplus eQ \subseteq_e Q$ ,  $N_Q(I \oplus eQ) = N_Q(I) + N_Q(e) = 1$ . Hence  $N_Q(e) > 1 - \varepsilon$ . Furthermore since  $l_{\bar{R}}(I) = l_{\bar{R}}(\bar{I})$ ,  $e\bar{I} = 0$ , where  $l_{\bar{R}}(\ )$  means the left annihilator ideal. In particular,  $ey = 0$ . Now since  $y = x - x'$ ,  $ex = ex'$ . Finally, we shall show that  $ex' \neq 0$ . Since  $ex = x - (1-e)x$ ,  $\bar{N}(ex) > \bar{N}(x) - \bar{N}((1-e)x) > \bar{N}(x) - \bar{N}(1-e) > \bar{N}(x) - \varepsilon$ . If we set  $\varepsilon$  as  $\bar{N}(x) > \varepsilon$ , then  $N(ex) \neq 0$ , so  $ex = ex' \neq 0$ . Therefore  $\bar{R}x \cap Q \neq 0$ , hence  $\bar{R}$  is a left essential extension of  $Q$ . This completes the proof.

REMARK. Recently, H. Kambara [2] constructed the counter example of Roos conjecture (=Is every directly finite regular right self-injective ring necessary left self-injective?). He constructed the simple regular ring which is directly finite right self-injective and satisfies the assumption of above Theorem 1, but not left self-injective. By virtue of this example, Theorem 1 is not abstract non-sense.

If  $N$  is a pseudo-rank function, then we have the following theorem.

**Theorem 2.** *Let  $R$  be a regular ring with pseudo-rank function  $N$ . If for any essential right ideal  $I$  of  $R$ ,  $N(I) = 1$  and  $\ker(N)$  is a prime ideal, then  $N$  is an extreme point and is extended to the maximal right quotient ring  $Q$ . In this case,  $Q/\ker N_Q$  is the maximal right quotient ring of  $R/\ker N$ , where  $N_Q$  is the extension  $N$ . Furthermore, the completion of  $R$  is isomorphic to the left maximal quotient ring of the right maximal quotient ring of  $R/\ker(N)$ .*

Proof. Let  $\bar{R}$  be the  $N$ -completion of  $R$ . Then since  $\bar{R}$  is a right and

left self-injective regular ring,  $\bar{R}$  is injective as a right  $R$ -module. Now there exists a  $R$ -module homomorphism  $f$  from  $Q$  to  $\bar{R}$  such that the following diagram commutes,

$$\begin{array}{ccc} Q & \xrightarrow{\quad f \quad} & R \\ \uparrow & & \uparrow \\ R & \longrightarrow & R/\ker(N) \end{array}$$

In this case, by using the same proof of Theorem 1, we can see that  $\bar{R}$  is a non-singular right  $R$ -module and  $f$  is a ring homomorphism. We extend  $N$  to  $Q$  as follows, for any element  $x$  of  $Q$ , we define that  $N_Q(x) = N(f(x))$ . Note that  $\ker(f) = \ker N$  and  $\ker N_Q \cap R = \ker N$ . Clearly  $R/\ker N$  has a rank function  $\bar{N}$  which is induced by  $N$ . We note that  $\bar{N}(K) = 1$  for any essential right ideal  $K$  of  $R/\ker N$ . Therefore we apply Theorem 1 to  $R/\ker N$ , that is  $\bar{R}$  is the maximal left quotient ring of the maximal right quotient ring of  $R/\ker N$ . Next we claim that  $Q/\ker N_Q$  is a right essential extension of  $R/\ker N$ . Given non-zero element  $x$  of  $Q/\ker N_Q$ , since  $x$  is in  $Q$ , there exists essential right ideal  $J$  of  $R$  such that  $xJ \subseteq R$ . Assume that  $xJ \subseteq \ker N$ , then  $x\bar{J} = \bar{0}$ . In this case, we have that  $x = 0$ , which is a contradiction. Therefore  $xJ \not\subseteq \ker N$ , that is for some non-zero element  $t$  of  $J$ ,  $\bar{0} \neq x\bar{t} \in R/\ker N$ . So  $Q/\ker N$  is essential right extension of  $R/\ker N$ . Note that  $\ker N_Q$  is a prime ideal of  $Q$ . Since  $Q$  is a self-injective regular ring, there exists a central idempotent  $e$  of  $Q$  such that  $\ker N_Q \subseteq_e eQ$ . Thus  $\ker N_Q \oplus (1-e)Q$  is an essential ideal of  $Q$ , so  $N_Q(\ker N_Q \oplus (1-e)Q) = 1$ . This shows that  $N_Q((1-e)Q) = 1$ . Now  $N_Q(e) = 0$ , hence  $\ker N_Q = eQ$ . Therefore  $Q/\ker N_Q = Q/eQ$  is a regular right self-injective ring. Consequently,  $Q/\ker N_Q$  is a maximal right quotient ring of  $R/\ker N$ . Thus  $Q/\ker N_Q$  is a prime regular self-injective ring with rank function. In this case, [1, Proposition 8.6] shows that  $Q/\ker N_Q$  is a simple ring. Therefore  $R/\ker N$  is also a simple ring. Now [1, Theorem 19.14] implies that  $N$  is an extreme point of  $P(R)$ . Thus the proof is complete.
