Osaka University
GEOMETRY OF PLANE CURVES VIA
TSCHIRNHAUSEN RESOLUTION TOWER

NORBERT A’CAMPO and MUTSUO OKA

(Received September 19, 1995)

1. Introduction.

The weight vectors of a resolution tower of toric modifications for an irreducible germ of a plane curve \( C \) carry enough information to read off invariants such as the Puiseux pairs, multiplicities, etc [29]. However, each step of the inductive construction of a tower of toric modifications depends on a choice of the modification local coordinates. This ambiguity makes it difficult to study the equi-singularity problem of a family of germs of plane curves or to study a global curve. It is the purpose of this paper to make a canonical choice of the modification local coordinates \((u_i,v_i)\) (Theorem 4.5), and to obtain a canonical sequence of germs of curves \( \{ C_i; i = 1, \ldots, k \} \) \( (C_k = C) \) such that the local knot of the curve \( C_i \) is a compound torus knot around the local knot of the curve \( C_{i-1} \). We will show that the local equations \( h_t(x,y) \) of the the germs \( \{ C_i; i = 1, \ldots, k \} \) are the Tschirnhausen approximate polynomials of the local equation \( f(x,y) \) for \( C \), provided that \( f(x,y) \) is a monic polynomial in \( y \).

The importance of the Tschirnhausen approximate polynomials was first observed by Abhyankar-Moh [3,4], and our work is very much influenced by them. However, our result gives not only a geometric interpretation of [3,4] but also a new method to study the equi-singularity problem, see [35], for a given family of germs of irreducible plane curves \( f(x,y,t) = 0 \) whose Tschirnhausen approximate polynomials \( h_t(x,y), i = 1, \ldots, k-1 \) do not depend on \( t \).

In section 6, we show that a family of germs of plane curves \( \{ f_t(x,y) = 0 \} \) with Tschirnhausen approximate polynomials \( h_t(x,y), i = 1, \ldots, k-1 \) not depending upon \( t \) and satisfying an additional intersection condition is equi-singular (Theorem 6.2). In section 8, we will give a new proof and a generalization of the Abhyankar-Moh-Suzuki theorem from the viewpoint of the equi-singularity at infinity (Theorems 8.2, 8.3, 8.7).

This work was done when the first author was visiting the Department of Mathematics of the Tokyo Institute of Technology in the fall of 1993. We thank the Dept. of Math. of T.I.T. for their support and hospitality.
2. Tschirnhausen approximate polynomials of a monic polynomial.

Let \( f(y) = y^n + \sum_{i=1}^n c_i y^{n-i} \) be a monic polynomial in \( y \) of degree \( n \) with coefficients in an integral domain \( R \) which contains the field of rational numbers \( \mathbb{Q} \), and let \( a \) be a positive integer such that \( a \) divides \( n \). The \( n/a \)-th Tschirnhausen approximate polynomial (or the \( n/a \)-th Tschirnhausen approximate root) of \( f(y) \) is the monic polynomial \( h(y) \in R[y] \) of degree \( a \) such that degree \( (f(y) - h(y)^{n/a}) < n - a \). The coefficients of \( h(y) = y^a + \sum_{i=1}^a c_i y^{a-i} \) are inductively determined by: \( c_0 = 1 \) and \( c_i(x) = \sum_{j=1}^i c_j(x) \) for \( i = 1, \ldots, a \). The coefficient \( c_j \) is a weighted homogeneous polynomial of degree \( j \) in the variables \( c_1, \ldots, c_a \) with weight \( c_j = j \), \( 1 \leq j \leq a \). In our application \( R \) will be the ring \( \mathbb{C}[x] \) or \( \mathbb{C}[x] \). For further detail, we refer to [3,4,32]. From the Euclidean division algorithm, it follows that

Proposition 2.1. Let \( h(y) \in R[y] \) be monic of degree \( a \) in \( y \), and let \( P(y) \in R[y] \) such that \( sa \leq \deg P(y) < (s+1)a \). Then there exists a unique expansion, called the Euclidian expansion, \( P(y) = \sum_{i=0}^s \alpha_i(y)h(y)^{i} \), where \( \alpha_i(y) \in R[y] \), \( i = 0, \ldots, s \), satisfy \( \deg \alpha_i(y) < a \). In particular, we can expand \( f(y) \) with respect to its \( n/a \)-th Tschirnhausen approximate polynomial, as \( f(y) = h(y)^{n/a} + \sum_{i=0}^{n/a} c_i(y)h(y)^{n/a-i} \), \( \deg \alpha_i(y) < a \). If \( f(y) = f(x,y) \in \mathbb{C}[x][y] \), the coefficients \( c_i(y) = c_i(x,y) \) are also polynomials in \( x \) and \( y \).

The second assertion is immediate from the Euclidean expansion of \( f - h^{n/a} \). We call the above expansion the \( n/a \)-th Tschirnhausen expansion of \( f(x,y) \). The expansion of \( P(x,y) \) with respect to \( h(x,y) \) will also be called the Tschirnhausen expansion if \( h(x,y) \) is a Tschirnhausen approximate polynomial. Tschirnhausen approximate polynomials behave hereditarily in the following sense.

Proposition 2.2. Assume that \( a,b \geq 2 \) are integers such that \( ab \mid n \). Let \( h \) and \( h' \) be respectively the \( n/a \)-th and \( n/ab \)-th Tschirnhausen approximate polynomials of \( f \) and let \( h' = h^b + \sum_{i=1}^b c_i h^{b-i} \), \( \deg c_i < a \), be the Tschirnhausen expansion of \( h' \) with respect to \( h \). The first coefficient \( c_1 \) is zero and \( h \) is the \( ab/a \)-th Tschirnhausen approximate polynomial of \( h' \).

Proof. With \( m := n/ab \), we have \( \deg(f - h^{mb}) < n - a \) and \( \deg(f - h'^m) < n - ab \). Using the expansion of \( h' \) with respect to \( h : h' = h^b + \sum_{i=1}^b c_i h^{b-i} \), \( \deg c_i < a \), we get

\[
h'^m = (h^b + c_1 h^{b-1})^m = h^{mb} + mc_i h^{mb-1} + R_1 + R_2,
\]

where \( R_1 := \sum_{i=2}^m c_i h^{mb-i} \) and \( R_2 := \sum_{i=2}^m c_i h^{mb-i} (\sum_{j=2}^m c_j h^{mb-j}) \). If \( c_1 \neq 0 \), we would first conclude \( \deg_R R_1 < n - a + \deg c_1 \), \( \deg_R R_2 < n - a \), and then
n - a > \deg_y(f - h^{mb}) = \deg_y(f - h'^{m} + mc_1 h^{mb - 1} + R_1 + R_2) \\
= \deg_y(c_1 h^{mb - 1}) \geq (mb - 1)a = n - a.

So \( c_1 = 0 \) and it follows that \( \deg_y(h' - h^b) = \deg_y(\sum_{i=2}^b c_i h^{b - i}) < ab - a \). By the uniqueness of the Tschirnhausen approximate polynomial, the above inequality implies that \( h \) is the \( ab / a \)-th Tschirnhausen approximate polynomial of \( h' \). Q.E.D.

The generalized binomial formula: \((1 + z)^r = \sum_{j=0}^r \binom{r}{j} z^j \) for \( r > 0 \), with coefficients \( \binom{r}{j} := \frac{r(r-1)\cdots(r-j+1)}{j!} \), converges for \( |z| < 1 \). When \( r \) is a rational number \( \frac{p}{q} \), the identity: \((1 + z)^{\frac{p}{q}} = (1 + z)^p \) gives a recurrent computation of the coefficients of \( (1 + z)^{\frac{p}{q}} \). In particular, with \( \text{Trunc}^{(l+z)^{\frac{p}{q}}} := \sum_{j=0}^l \binom{\frac{p}{q}}{j} z^j \), it follows that

\[
\text{val}_y((1 + z)^r - \text{Trunc}^{(l+z)^{\frac{p}{q}}}) > \varepsilon
\]

For a real number \( x \in \mathbb{R} \), denote by \([x]\) the largest integer \( n \) such that \( n \leq x \).

**Lemma 2.3.** Assume that \( a, b, c, d \) are positive integers such that \( \gcd(a,b) = 1 \) and that \( d \) divides \( ac \). Let \( F(y,z) = (y^a + z^b)^c \) and \( H(y,z) = y^{ac/d} \text{Trunc}^{(l+z)^{\frac{p}{q}}(1 + z)^{\frac{p}{q}}/y^a} \). Then \( H \) is the \( d \)-th Tschirnhausen approximate polynomial of \( F(y,z) \) as a polynomial of \( y \).

Proof. The polynomials \( F(y,z) \) and \( H(y,z) \) are weighted homogeneous of degree \( abc \) and \( abc/d \) respectively with respect to the weight vector \( P = (b,a) \). In particular, the monomials in \( F(y,z) \) and \( H(y,z) \) have the form \( y^i z^j \) with \( i + j = c \). Note also that \( \deg_y(F,y,z) = ac \), \( \deg_y(H = ac/d \) and \( \deg_y(F - H) < ac - a[c/d] \) by (2.2.1). As \( ac - ac/d > ac - a[c/d] - a \), this implies the inequality: \( \deg_y(F(y,z) - H(y,z)) < ac - ac/d \). Q.E.D.

**3. Toric modifications and strict transforms**

**3.1. Basic properties of toric modifications** (see [26,29,30,33]). Let \((x,y)\) be a fixed system of local (or global) coordinates of \( C^2 \) at the origin. Let \( N \) be the lattice of integral weights for the monomials in \((x,y)\). The weights \( E_1(x^a y^b) = a \) and \( E_2(x^a y^b) = b \) span the lattice \( N \), and a weight \( \alpha E_1 + \beta E_2 \) will be denoted by the integral column vector \((\alpha, \beta)\). Let \( N^+ \) be the space of positive weight vectors of \( N \), and similarly let \( N_{R+}^+ \) be the positive cone in \( N := N \otimes \mathbb{Z} \). A simplicial cone subdivision \( \Sigma \) of \( N_{R+}^+ \) is a sequence \((T_1, \cdots, T_m)\) of primitive weights in \( N^+ \), called the vertices, such that \( T_0 = E_1, T_{m+1} = E_2 \) and \( \det(T_i, T_{i+1}) = \det(E_1, E_2) \) for each \( i = 0, \cdots, m \). The \( m+1 \) cones \( \text{Cone}(T_i, T_{i+1}) := \{ tT_i + sT_{i+1} : t, s \geq 0 \} \) cover without overlap the cone \( N_{R+}^+ \). The subdivision \( \Sigma \) is called regular if \( \det(T_i, T_{i+1}) = 1 \) for each \( i = 0, \cdots, m \). Let \( \sigma_i \) be the integral matrix mapping \( E_1 \) to \( T_i \) and \( E_2 \) to \( T_{i+1} \).

Using a birational mapping \( \phi_M : C^2 \to C^2 \), \( \phi_M(x,y) = (x^a y^b, x^c y^d) \) for an integral
unimodular matrix $M = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$, the toric modification $p : X \to C^2$ associated with a regular simplicial cone subdivision $\Sigma^s$ is defined as follows. The non-singular complex manifold $X$ is covered with $m+1$ so-called toric coordinate charts $\{C_{a_i}, (x_{a_i}, y_{a_i})\}$, $i = 0, \ldots, m$, where points $(x_{a_i}, y_{a_i})$ and $(x_{a_j}, y_{a_j})$ are identified if and only if the birational map $\phi_{a_i}^{-1} a_i$ is defined at the point $(x_{a_i}, y_{a_i})$ and $(x_{a_j}, y_{a_j}) = (x_{a_i}, y_{a_i})$. The morphism $\pi_{a_i} : C_{a_i} \to C^2$ defined by $\pi_{a_i}(x_{a_i}, y_{a_i}) = (x_{a_i}, y_{a_i})$ is compatible with the identifications and define a proper birational analytic map $p : X \to C^2$. A toric modification is a composition of finite blowing-ups (see [18]). The exceptional divisor $p^{-1}(O)$ is the union of $m$ rational curves $\{E(T_0); i = 1, \ldots, m\}$ and each one is covered by its left chart $C_{a_i}$ and its right chart $C_{a_i}$ and defined by the equations $\{x_{a_i} = 0\}$. Thus only $E(T_0)$ and $E(T_{i+1})$ intersect transversely at the origin of the chart $C_{a_i}$. The non-compact divisors $E(T_0) = \{x_{a_0} = 0\}$ and $E(T_0) = \{y_{a_m} = 0\}$ map isomorphically onto the axis $x = 0$ and $y = 0$.

3.2. Admissible toric modifications. Let $f(x, y) = \Sigma a_{\alpha, \beta} x^\alpha y^\beta$ be the Taylor expansion of a germ of a holomorphic function $f$ with $f(O) = 0$. The Newton polygon $\Gamma_+(f; (x, y))$ of $f(x, y)$ is the convex hull in $N_+^R$ of $\{(\alpha + s, \beta + t) \in R^2; a_{\alpha, \beta} \neq 0, s \geq 0, t \geq 0\}$ and the Newton boundary $\Gamma(f; (x, y))$ is the union of the compact faces of $\Gamma_+(f; (x, y))$ (see [26,27,29] for instance). The Newton boundary $\Gamma(f; (x, y))$ contains only a finite number of faces of dimension one. Each positive weight vector $P = (p, q) \in N_+^R$ defines a non-negative function on $\Gamma_+(f; (x, y))$, for which we denote by $d(P; f)$ its minimal value and by $\Delta(P; f)$ the face or the vertex where this minimal value is taken. We consider on $N_+^R$ the equivalence relation: $P \sim Q$ if and only if $\Delta(P; f) = \Delta(Q; f)$. The dual Newton diagram $\Gamma^s(f; (x, y))$ of $f(x, y)$ is the conical subdivision of $N_+^R$ given by the equivalence classes. Let $P_i = (q_i, r_i) \in N_+^R$, $i = 1, \ldots, m$ be the ordered list of primitive weight vectors such that $\Delta(P_i; f)$ is the list of the one-dimensional faces of $\Gamma^s(f; (x, y))$ and $d(P_{i+1}) = (a_{i+1} - a_{i+1} b_i, 0), i = 1, \ldots, m-1$. The face function $f_p(x, y) = \Sigma_{(\alpha, \beta) \in M(P_i; f)} a_{\alpha, \beta} x^\alpha y^\beta$ admits a product decomposition $f_p(x, y) = c_i x_i y_i \Pi_{j=1}^{m-1} (y^{\gamma_{i,j}} - y_i) x_i y_i$ with distinct non-zero complex numbers $\gamma_{i,1}, \ldots, \gamma_{i,k_i}$. Recall that $f(x, y)$ is non-degenerate if and only if $\gamma_{i,j} = 1$ for any $i, j$. The partial sum $\Sigma(f)(x, y) = \Sigma^p a_{\alpha, \beta} x^\alpha y^\beta$ over all $(\alpha, \beta) \in \Gamma(f; (x, y))$ is the Newton principal part $\Sigma(f)(x, y)$.

A regular simplicial cone subdivision $\Sigma^s$ with vertices $\{T_0 = E_1, T_1, \ldots, T_b, T_{i+1} = E_2\}$ is called admissible for $f(x, y)$ if $\Sigma^s$ is a refinement of the dual Newton diagram $\Gamma^s(f; (x, y))$, meaning $P_i = (q_i, r_i) \in \{T_0, T_1, \ldots, T_b, T_{i+1}\}, i = 1, \ldots, m$. Note that $\Sigma^s$ is admissible for $f(x, y)$ if and only if $\Delta(T_j; f) \cap \Delta(T_{j+1}; f) \neq \emptyset, j = 0, \ldots, \ell$. The corresponding toric modification $p : X \to C^2$ is called admissible for $f(x, y)$.

Basic properties of admissible toric modifications are:

(3.2.A) The divisor $E(T_j)$ meets the proper transform $C$ if and only if $T_j$ is a...
primitive weight $P_1$.

(3.2.B) The divisor $\hat{E}(P_i)$ intersects $\bar{C}$ at $k_i$ points. In the right toric chart $\{C_{x,y}(x_{y},y_{x})\}$, $\sigma_j = \text{Cone}(T_p, T_{j+1})$, $P_i = T_j$, the intersection $\bar{C} \cap \hat{E}(P_i)$ is $\{(0, y_{i,1}), \ldots, (0, y_{i,k_i})\}$.

(3.2.C) The divisor of the pull back $p^* f$ of the function $f$ is given by

$$
(p^* f) = \sum_{i=1}^{m} \sum_{j=1}^{k_i} \bar{C}_{i,j} + \sum_{j=0}^{\ell+1} d(T_j; f) \hat{E}(T_j)
$$

where $\bar{C}_{i,j}$ is the union of components of $\bar{C}$ which pass through $(0, y_{i,j})$.

(3.2.D) If $f(x,y)$ is irreducible as a germ of a function at the origin, then $m = 1$ and $k_1 = 1$.

(3.2.E) If $f$ is non-degenerate, the curve $\bar{C}_{i,j}$ is smooth and $\bar{C}_{i,j}$ intersects transversely with $\hat{E}(P_i)$. Thus, if $f(x,y)$ is non-degenerate, the modification $p$ is a good resolution of $f(x, y)$ (see [18]).

### 3.3. Intersection multiplicity with a reduced irreducible germ.

Let $C = \{f(x, y) = 0\}$ be a reduced irreducible germ of a curve. The defining function admits for a weight $P_1 = (a_1, b_1)$ an initial expansion $f(x, y) = (a_1^x + \xi_1^y)^{A_2} + \text{(higher terms)}$ with $\xi_1 \neq 0$ and $\text{gcd}(a_1, b_1) = 1$, where "higher terms" collects the monomials of $P_1$-degree strictly greater than $a_1 b_1 A_2$. Let $C'$ be another (not necessarily irreducible) germ of a curve defined by $C' = \{(x, y) \in U; g(x, y) = 0\}$. Let $p: X \to C'$ be a toric modification admissible both for $C$ and $C'$, and let $\Xi_1$ be the intersection point of $\bar{C}$ and $E(P_1)$. Then

**Proposition 3.3.1** (Lemma 7.12, [29]). The intersection multiplicity of $C$ and $C'$ at the origin is $I(C, C'; O) = d(P_1; g) A_2 + I(\bar{C}, \bar{C}'; \Xi_1)$. The term $I(\bar{C}, \bar{C}'; \Xi_1)$ vanishes if and only if $g_{P_1}(x, y)$ is not divisible by $(y^{a_1} + \xi_1^y)^{A_2}$. If $g(x, y)$ has for a primitive weight vector $P'_1 = (a'_1, b'_1)$ the initial expansion $g(x, y) = (y^{a'_1} + \xi'_1^y)^{A'_2} + \text{(higher terms)}$, then $d(P_1; g) A_2 = \min(a_1 b_1, a'_1 b'_1) \times A_2 A'_2$ and moreover $I(\bar{C}, \bar{C}'; \Xi_1) = 0$ if and only if either $P_1 \neq P'_1$ or $P_1 = P'_1$ and $\xi_1 = \xi'_1$.

### 3.4. A resolution tower of toric modification for an irreducible germ.

Let $C$ be an irreducible germ of a plane curve and let

$$
\mathcal{T} = \{X_k \to X_{k-1} \to \cdots \to X_1 \to X_0\}
$$

be a sequence of non-trivial toric modifications where each $p_{i+1}: X_{i+1} \to X_i$ is the toric modification associated with a regular simplicial cone subdivision $\Sigma_k$ of the cone $N_k$ in the space of weights for a local system of coordinates $(u_i, v_i)$ of $X_i$, centered at the center $\Xi_i \in X_i$ of the modification $p_{i+1}$. Let $E_{i,1}, \ldots, E_{i,n_i}$ be the exceptional divisors of $p_i: X_i \to X_{i-1}$. By abuse of the notation, we denote by the
same $E_{i,j}$, the strict transform of $E_{i,j}$ to $X_\ell$ for any $\ell \geq i$. Thus the exceptional divisors of the modification $\Phi_k := p_1 \circ \cdots \circ p_k : X_k \to X_0$ are $\{E_{i,j}\}$, $1 \leq i \leq k$, $1 \leq j \leq s_i$. Denote by $\Xi_i \in E_{i,\beta_i} \cap C^{(0)}$ the preimage of the singularity in the strict transform $C^{(0)}$ of $C$ to $X_i$. We call $\mathcal{F}$ a resolution tower of admissible toric modifications if the following conditions are satisfied ([29]).

(i) $X_0$ is an open neighborhood of the origin $O$ of $C^2$, $(u_0, v_0) = (x, y)$ and $\Xi_0 = O$.
(ii) The modification $p_{i+1} : X_{i+1} \to X_i$ is non-trivial and admissible for $\Phi_i^* f(u_\iota, v_\iota)$, $i > 0$.
(iii) The coordinate $u_i$ is simply the restriction $u_i = x_{\sigma_i}$ of the coordinate $x_{\sigma_i}$ of the right toric chart of $E_{i,\beta_i}$ to a neighborhood $W_i$ of $\Xi_i$.
(iv) $p_i(\Xi_i) = \Xi_{i-1}$.
(v) The composition $\Phi_k : X_k \to X_0$ is a good resolution of $C$.

The weight vectors $P_i = (a_i, b_i)$ corresponding to the exceptional divisors $E_{i,\beta_i}$ for $i = 1, \ldots, k$ are the weight vectors of the tower ([29]). If the tower $\mathcal{F}$ is admissible for $C$, there exist for $i = 0, \ldots, k-1$ non-zero complex numbers $\xi_i \in C$ so that $C^{(0)} = \{(u_\iota, v_\iota) \in W_i ; (v_{i+1}^{a_i+1} + \xi_i + u_i^{b_i})^{A_i+2} + \text{(higher terms)} = 0\}$, where $C^{(0)} = C$ and $A_j = a_j \cdots a_k$, $j \leq k$ and $A_{k+1} = 1$.

Let $D = \{(x, y) \in C^2 ; g(x, y) = 0\}$ be an irreducible, not necessarily reduced, germ of a plane curve at the origin of $C^2 = X_0$ and let $D^{(0)}$ be the strict transform of $D$ to $X_i$. If $D$ has the same toric tangential direction of depth $\theta$ with $C$ with respect to $\mathcal{F}$, i.e. if $\Xi_i \in D^{(0)}$ for $i \leq \theta$ and $\Xi_{\theta+1} \notin D^{(\theta+1)}$, there exist a non-zero complex number $\xi_{\theta+1}$, a positive integer $A_{\theta+2}$, and a primitive weight vector $(a_{\theta+1}, b_{\theta+1})$ such that

\begin{equation}
D^{(0)} = \begin{cases}
\{(u_\iota, v_\iota) \in W_i ; (v_{i+1}^{a_i+1} + \xi_i + u_i^{b_i})^{A_i+2} + \text{(higher terms)} = 0\}, & i < 0 \\
\{(u_\iota, v_\iota) \in W_i ; (v_{\theta+1}^{a_{\theta+1}} + \xi_{\theta+1} + u_{\theta+1}^{b_{\theta+1}})^{A_{\theta+2}} + \text{(higher terms)} = 0\}, & i = 0
\end{cases}
\end{equation}

where $A_j = a_j \cdots a_{\theta+1}A_{\theta+2}$, $j \leq \theta + 1$. If $P_{\theta+1} = (1, 0)$, the transform $D^{(\theta)}$ is defined by $\{v_{\theta+1}^{A_{\theta+2}} = 0\}$ since $D$ is irreducible. The case $P_{\theta+1} = (0, 1)$ does not occur as $\{u_{\theta+1} = 0\}$ is nothing but $\bar{E}(P_\theta)$. Put

\[ I(P_{\theta+1}, P_{\theta+1}) := \begin{cases}
\min(a_{\theta+1}, b_{\theta+1}) & \text{if } a_{\theta+1}b_{\theta+1}, a_{\theta+1}b_{\theta+1} > 0 \\
b_{\theta+1} & \text{if } P_{\theta+1} = (1, 0)
\end{cases} \]

By induction, using Proposition (3.3.1), we get

**Lemma 3.4.2 ([29]).** Assume that $D$ has the same toric tangential direction of depth $\theta$ with $C$ with respect to $\mathcal{F}$. Under the assumption (3.4.1) on $D$, the local intersection multiplicity is

\[ I(C, D ; O) = \sum_{i=1}^{\theta} a_i b_i A_{i+1} A_{i+1}^i + I(P_{\theta+1}, P_{\theta+1}) \times A_{\theta+2} A_{\theta+2} \]
Let $D_1, \ldots, D_r$ be the irreducible components of a reducible plane curve germ $D$. We say that the reducible germ $D$ has the same toric tangential direction of depth $\theta$ with $C$ with respect to $T$ if $\Xi_t \in D_j^{(0)}$ for any $j = 1, \ldots, r$ and $i \leq \theta$ and $\Xi_{i+1} \notin D_j^{(0+1)}$ for some $j_0$.

4. A Tschirnhausen resolution tower for an irreducible germ

**Lemma 4.1.** Let $p : X \to \mathbb{C}^2$ be a toric modification with respect to a regular simplicial cone subdivision $\Sigma^*$ of $N^*$. Let $\sigma = \text{Cone}(P, P')$ be a cone in $\Sigma^*$ and $g(x, y) \in \mathbb{C}[x, y]$, such that $\Delta(P; g)$ is a vertex. At each point $\Xi \in \hat{\Delta}(P) - \bigcup_{Q \neq P} \hat{\Delta}(Q)$ the function $p^* g / x_\sigma^{(P; g)}$ is a unit.

Proof. Let $(v_1, v_2) = \Delta(P; g)$ and $c \neq 0$ be the coefficient of $x^{v_1} y^{v_2}$ in $g(x, y)$. Then the pullback $p^* g$ factors $x_\sigma x_{P'} y_\sigma y_{P'}$ for some analytic function $\Delta(P; g)$ and $\alpha \geq 0$. Moreover, $\alpha = 0$ if and only if $\Delta(P; g) = \Delta(P; g)$. In conclusion, $p^* g / x_\sigma^{(P; g)}$ is a unit at $\Xi$ since $y_\sigma$ is. Q.E.D.

In particular, if $P = (a, b)$ and $\Gamma(g; (x, y)) \subset \{ (v_1, v_2); v_2 < a \}$ or if $g(x, y) \in \mathbb{C}[x][y]$ and $\text{deg}_g < a$, the face $\Delta(P; g)$ is a vertex, and the lemma applies.

A. Tschirnhausen resolution tower

4.2. Let $f(x, y) \in \mathbb{C}[x][y]$ be monic of degree $n$ and irreducible with the initial expansion

$$f(x, y) = (y^{a_1} + \xi_1 x^{b_1}) a_2 + (\text{higher terms}), \quad a_1 > 1$$

for the primitive weight vector $P_1 = (a_1, b_1)$ with $n = a_1 A_2$. The $n/a$-th Tschirnhausen approximate polynomial $H_n(x, y)$ is a monic polynomial of degree $a_1$ in $y$ and defines at the origin the germ of the curve $D_{a_1} = \{ H_n(x, y) = 0 \}$.

4.3. First observation. Let $p_1 : X_1 \to \mathbb{C}^2$ be an admissible toric modification with respect to a regular simplicial cone subdivision $\Sigma_0^*$ for $f(x, y)$. The strict transform $C^{(1)}_1$ of $C$ to $X_1$ intersects only with $\hat{\Delta}(P_1)$, say at the point $\Xi_1$. In the chart $C_1^2$, where $P_1' = (a_1', b_1')$ and $\sigma_1 = (P_1, P_1')$ is the right cone of $\hat{\Delta}(P_1)$, we have $\Xi_1 = (0, -\xi_1)$. Put $h_1(x, y) := H_{a_1}$, $C_1 := D_{a_1}$. For a multiple $a$ of $a_1$ with $a | n$, the $A_2$-th (resp. $n/a$-th) Tschirnhausen approximate polynomial of $(y^{a_1} + \xi_1 x^{b_1})^{a_1}$ is the face function $h_1(x, y)$ (resp. $H_{a_1}$), hence $h_1$ and $H_{a_1}$ can be written as:

$$h_1(x, y) = (y^{a_1} + \xi_1 x^{b_1})(\text{higher terms}), \quad H_{a_1}(x, y) = (y^{a_1} + \xi_1 x^{b_1}) (\text{higher terms}), \quad |a_1| a$$

In particular, $h_1(x, y)$ is non-degenerate. As $p_1^*(y^{a_1} + \xi_1 x^{b_1}) = x_1^{a_1} y_1^{a_1} (y_1 + \xi_1)$, we
can write \( p_1^*h_1(x_{\sigma_1}, y_{\sigma_1}) = x_{\sigma_1}^a y_{\sigma_1}^b ((y_{\sigma_1} + \xi_1) + x_{\sigma_1} R(x_{\sigma_1}, y_{\sigma_1}), \quad R(x_{\sigma_1}, y_{\sigma_1}) \in C[x_{\sigma_1}, y_{\sigma_1}] \).

The functions

\[ u_1 = x_{\sigma_1}, \quad v_1 = p_1^*h_1 / x_{\sigma_1}^a y_{\sigma_1}^b ((y_{\sigma_1} + \xi_1) + x_{\sigma_1} R(x_{\sigma_1}, y_{\sigma_1})) \]

give a system of coordinates \((u_1, v_1)\) in a neighbourhood \( W_1 \) of \( \Xi_1 \). The strict transform \( C_1^{(1)} \) of \( C \) to \( X_1 \) intersects only with \( \tilde{E}(P_1) \) and \( p_1^*h_1 = u_1^a v_1^b \), \( C_1^{(1)} \) \( v_1 = 0 \), so \( C_1 \) is irreducible and \( p_1 \) is a good resolution of \( C_1 \).

If \( A_2 = 1 \), we have \( f = h_1 \) and we have nothing to do further. If \( A_2 \geq 2 \), the pull back \( p_1^*f(u_1, v_1) \) has an initial expansion

\[ (4.3.2) \quad p_1^*f(u_1, v_1) = u_1^a v_1^b (v_1^2 + \xi_2 u_1^2) A_3 + \text{(higher terms)} \]

with primitive weight vector \( P_2 = (a_2, b_2) \) where the multiplicity of \( \Phi^*f \) on \( E_1 \) is \( m_1(f) = a_1 b_1 A_2 \) by (4.2.1). Note also \( A_2 = a_2 A_3 \) and \( l(C_1, C; O) = a_1 b_1 A_2 + b_2 A_3 \) by Lemma 3.4.2. The advantage of the “Tschirnhausen coordinates” is the inequality \( a_2 \geq 2 \). In fact, in the Tschirnhausen expansion \( f(x, y) = h_1(x, y)^{A_2} + \Sigma_{j=2}^{A_3} c_j(x, y) h_1(x, y)^{A_2 - j} \) of \( f(x, y) \) with respect to \( h_1 \) we have \( c_j(x, y) \in C[x, y] \) and \( \deg c_j(x, y) < a_1, j = 2, \ldots, A_2 \), so the face \( \Delta(P_1, c) \) is necessarily a vertex. Therefore by the definition of the coordinate \((u_1, v_1)\) and Lemma 4.1 in a smaller neighbourhood \( W_1 \) of \( \Xi_1 \) the pull-backs are: \( p_1^*h_1(u_1, v_1) = u_1^a v_1^b \) with \( m_1(h_1) = a_1 b_1 \) and \( p_1^*c_j(u_1, v_1) = u_1^m U_j \), where \( m_j = d(P_1, c_j) \) and \( U_j \) is a unit for \( j \geq 2 \) with \( c_j \neq 0 \). If \( c_j = 0 \), we put \( U_j = 0 \) for simplicity. Thus we have

\[ (4.3.3) \quad p_1^*f(u_1, v_1) = (u_1^m v_1^b u_1^j) A_2 + \sum_{j=2}^{A_3} u_1^m v_1^j U_j (u_1^m v_1^b)^{A_2 - j}, \]

hence, with \( Q_0 = (m_1(h_1) A_2, a_2) \) and \( Q_j = (m_j + (A_2 - j) m_1(h_1), A_2 - j) \), the Newton polygon \( \Gamma_+(p_1^*f; (u_1, v_1)) \) is the convex hull of the sets \( \{Q_0 + R_j^2\} \) and \( \{Q_j + R_j^2\} \), \( 2 \leq j \leq A_2 \), \( c_j \neq 0 \). The Newton principal part \( N(p_1^*f)(u_1, v_1) \) contains \((m_1(f) + b_2, A_2 - a_2)\) by (4.3.2). It follows that \((m_1(f) + b_2, A_2 - a_2) = Q_j \) for \( j = 0 \) or for some \( j \geq 2 \), hence \( a_2 \geq 2 \). Moreover, if \( c_j \neq 0 \), we have \( d(P_2; p_1^*c_j h_1^{A_2 - j}) \geq d(P_2; p_1^*f) \), with equality if and only if \( a_2 \mid j \).

Let \( a_1 \mid a \) and \( a \mid n \). The following Tschirnhausen expansions start at \( j = 2 \) by Proposition 2.2:

\[ (4.3.4) \begin{align*}
H_a &= h_1^{a_1} + \Sigma_{j=2}^{a_1} d_j h_1^{a_1 - j} \in C[x][h_1], \quad \deg d_j < a_1 \\
f &= H_a^{a_2} + \Sigma_{j=2}^{a_2} c_j H_a^{a_2 - j} \in C[x][H_a], \quad \deg c_j < a
\end{align*} \]

By (4.3.3), the principal part of \( p_1^*f(u_1, v_1) \) with respect to the weight vector \( P_2 \) is

\[ (4.3.5) \quad p_1^*f_{P_2}(u_1, v_1) = u_1^m (v_1^2 + \xi_2 u_1^2)^{A_3} \]

With \( R_a := \Sigma_{j=2}^{a_2} c_j H_a^{a_2 - j} \), we have that \( \deg R_a < n - a \) and therefore the Tschirnhausen
expansion of $R_a$ with respect to $h_1$ can be written as $R_a = \sum_{\beta \in C(x)[y]} \beta \cdot h_1^\beta$ for some $\beta \in C(x)[y]$ and $\deg_\beta \beta \beta < a_1$. If $\beta \neq 0$, we can write $p^* \beta \cdot h_1^\beta = U \cdot u_1^\beta v_1^\beta$ by Lemma 4.1 for a unit $U$ and a non-negative integer $\gamma \in \mathbb{N}$. Thus we have for the Newton principal part

\[(4.3.6)\quad \deg_{\gamma_1}(p^* R_a)(u_1, v_1) \leq A_2 - a / a_1 - 1.\]

So, comparing the pull-back $p^* f(u_1, v_1) = p^* H_a^{n/a} + \Sigma_{i=2}^n U \cdot u_1^\beta v_1^\beta$ of (4.3.4) and (4.3.5), we see that the monomials $u_1^{m(f)} \times (v_1^{n/a} + \beta \gamma_1 v_1^i) \gamma_1 = \gamma_1$ of $u_1^{m(f)} v_1^a + \beta \gamma_1 v_1^a$ for $i > A_3 - a / a_1 - 1 / a_2$ come from $p^* H_a^{n/a}$. The expansions (4.3.4) and (4.3.1) give with some analytic functions $g_a, G_a$

\[(4.3.7)\quad \begin{align*}
p^* H_a^a(u_1, v_1) &= u_1^{m(H_a)}(v_1^{n/a} + u_1 G_a(u_1, v_1)) \\
p^* H_a^{n/a}(u_1, v_1) &= u_1^{m(f)}(v_1^{n/a} + u_1 G_a(u_1, v_1))
\end{align*}\]

Note that $m_1(H_a) n / a = m_1(f)$. Applying the above argument to $p^* H_a(u_1, v_1)$, we can conclude that the Newton boundary $\Gamma(p^* H_a; (u_1, v_1))$ is situated in the region $\{(v_1, v_2) \in \mathbb{R}^2; 0 \leq v_2 \leq a / a_1\}$ and that $B_a := (m_1(H_a), a / a_1)$ is the vertex of the left end of $\Gamma(p^* H_a; (u_1, v_1))$ by (4.3.7). Note also that $(n / a) B_a = (m_1(f), A_2)$ is the left end of $\Gamma(p^* f; (u_1, v_1))$ by (4.3.7). Let $\Delta_a$ be the first face of $\Gamma(p^* H_a)$ which contains $B_a$ and let $Q = (p_2, q_2)$ be the weight vector of $\Delta_a$.

**Assertion 4.3.8.** The inequality $q_2 / p_2 \geq b_2 / a_2$ holds.

Proof. Assuming by contradiction that $q_2 / p_2 < b_2 / a_2$, we have $p^* f(q(u_1, v_1)) = u_1^{m(f)} v_1^{a_2}$, and we will prove the assertion by excluding the following three cases:

(a) $d(Q; p^* H_a^{n/a}) > d(Q; p^* R_a)$, (b) $d(Q; p^* H_a^{n/a}) < d(Q; p^* R_a)$, (c) $d(Q; p^* H_a^{n/a}) = d(Q; p^* R_a)$. Figure (4.3.A) indicates the respective situations. In case (a), $u_1^{m(f)} v_1^{a_2} = (p^* R_a)_q(u_1, v_1)$ holds, which is impossible by (4.3.6). The case (b) is impossible as $(p^* H_a)_q(u_1, v_1)^{n/a} \neq u_1^{m(f)} v_1^{a_2}$ by the assumption. If case (c) holds, from (4.3.6) it follows $(p^* H_a)_q(u_1, v_1)^{n/a} = (p^* R_a)_q(u_1, v_1) \neq 0$, and then $d(Q; p^* H_a^{n/a}) = d(Q; p^* R_a)$.
\[ = d(Q; p^* f) \text{ and finally the equality } u^{m(f)} v^2 = (p^* h^0) q(u_1, v_1)^{n/a} + (p^* r^0) q(u_1, v_1). \] But this equality is impossible. In fact, let us write \((p^* h^0) q(u_1, v_1) = u^{m(f)} v^2 + n/a + \gamma u_1^2 v_1^2 + S(u_1, v_1)\) where \(\gamma \neq 0, 0 \leq \beta_1 < a/a_1\) and \(\text{deg}_{v_1} S(u_1, v_1) < \beta_1\) if \(S \neq 0\). Then \((p^* h^0) q(u_1, v_1) = u^{m(f)} v^2 + n/a + \gamma u_1^2 v_1^2 + S(u_1, v_1)\) with \(\text{deg}_{v_1} S < \beta_1\), where \(\alpha_1 = \alpha_1 + (n/a - 1)m_1(U_1)\) and \(\beta_1 = A_2 - a/a_1 + \beta_1 \geq A_2 - a/a_1\). On the other hand, the second term of the right side of the equality has no monomial \(u_1^2 v_1^2\) with \(v_2 \geq A_2 - a/a_1\).

Q.E.D.

By Assertion 4.3.8, the face function \((p^* h^0) f_1, u_1, v_1)\) for the weight vector \(P_2\) is divisible by \(u^{m(f)} v_1\), hence \(H^1(u_1, v_1) := (p^* h^0) f_1, u_1, v_1) / u^{m(f)} v_1\) is a polynomial. By a similar discussion as above, we conclude: \(d(P_2; p^* f(u_1, v_1)) = d(P_2; p^* h^0) f_1, u_1, v_1) = (p^* h^0) f_2, u_1, v_1) = \) \((p^* h^0) f_2, u_1, v_1) = u^{m(f)} v_1^2 + n/a + \gamma u_1^2 v_1^2 + S(u_1, v_1)\) with \(\text{deg}_{v_1} S < \beta_1\). In other words, \(H^1(U_1, v_1)\) is the \(n/a\)-th Tschirnhausen approximate polynomial of \((u_1^2 + \xi_2 u_2^2)^{n/a}\). In particular, if \(a_1 a_2\) divides \(A_2/(n/a) = a/a_1 a_2\) on an integer and we can see easily that \(H^1(u_1, v_1) = (u_1^2 + \xi_2 u_2^2)^{n/a}\) if \(a_1 a_2\) divides \(a\) and \(p^* H^1(u_1, v_1) = u^{m(f)} v_1^2 + n/a + \gamma u_1^2 v_1^2 + S(u_1, v_1)\) + (higher terms). Putting \(h_2 = H_{a_1 a_2}, C_2 = D_{a_1 a_2}\) and \(a = a_1 a_2\), we observe that \(p^* h^2(u_1, v_1) = u^{m(f)} v_1^2 + \xi_2 u_2^2\) + (higher terms) and therefore \(p^* h^2(u_1, v_1)\) is clearly non-degenerate.

4.4. Inductive construction of a tower. Let \(\mathcal{T}_j = \{X_j \rightarrow X_{j-1} \rightarrow \cdots \rightarrow X_1 \rightarrow X_0 = \mathbb{C}^2\}\) be a tower of toric modifications with the corresponding weight vectors \(P_i = \{a_i, b_i\}\) such that \(a_1 \cdots a_j | n\) and \(a_i \geq 2, i = 1, \ldots, j\). Put \(A_{i+1} := n/a_1 \cdots a_i, i \leq j\) and for simplicity \(h(x, y) = H_{a_1 \cdots a_i}(x, y), C_i = D_{a_1 \cdots a_i}\) and \(\Phi_i = p_1 \circ \cdots \circ p_i; X_1 \rightarrow X_0\). Let \(D_a^0\) and \(C_i^0, (i \geq l)\) be the strict transforms of \(D_a\) and \(C_i\) to \(X_l\) respectively. The map \(p_i: X_i \rightarrow X_{i-1}\) is an admissible toric modification for \(\Phi_{i-1} \circ f\) associated with a regular simplicial cone subdivision \(\Sigma_i - 1\). Let \(\Xi_i = C_i^0 \cap X_i\) be the center of the modification \(p_i + 1\) and let \((u_i, v_i)\) be the chosen modification local coordinate system with the center \(\Xi_i\) so that \(\{u_i = 0\}\) is the defining equation of the exceptional divisor \(E_i := E(P_i)\) for \(i = 1, \ldots, j\). We assume the following properties (1-j), (2-j) and (3-j) for the tower.

1) \((C_i, O)\) is a germ of an irreducible curve at the origin for \(i = 1, \ldots, j\) and the strict transform \(C_i^0\) to \(X_i\) is smooth and is defined by \(\{v_i = 0\}\). The pull backs of \(f\) and \(h_i, i \leq j\) equal:

\[(4.4.1) \quad \Phi_i^* f(u_i, v_i) = \begin{cases} u_i^{m(f)} v_i, & i = j \text{ and } A_{j+1} = 1 \\ u_i^{m(f)} v_i^{i+1} + \xi_{i+1} u_i^{m(f)} v_i^{i+1} + \text{(higher terms), otherwise} \end{cases}\]

\[(4.4.2) \quad \Phi_i^* h(u_i, v_i) = \begin{cases} u_i^{m(h)} v_i, & i = l \\ u_i^{m(h)} v_i^{i+1} + \xi_{i+1} u_i^{m(h)} v_i^{i+1} + \text{(higher terms), otherwise} \end{cases}\]
The modification coordinates \((u_i, v_i)\) are characterized by (4.4.2). We assume \(a_{j+1} \geq 2\) in (4.4.1), if \(A_{j+1} \geq 2\). More generally, for any positive integer \(a\) with \(a \mid n\) and \(a \cdots a_{i+1} \mid a\), we have

\[
\Phi^*_i H_{a}(u_i, v_i) = u_i^{m_i(h_{i+1})} (v_i^{a_{j+1}} + \xi_i^{a_{j+1}} 1^{a_{i+1}} + \text{(higher terms)}
\]

Here \(m_i(h_i)\), \(m_{i}(H_{a})\) and \(m_{i}(f)\) are the respective multiplicities of the pull backs \(\Phi^*_i h_i\), \(\Phi^*_i H_{a}\) and \(\Phi^*_i f\) on the exceptional divisor \(E_i\) and they satisfy the equalities:

\[
m_i(h_i) \times A_{i+1} = m_{i}(H_{a}) \times n / a = m_{i}(f)
\]

\[
m_i(f) = a_1 b_1 A_2, \quad m_i(f) = a_1 m_{i-1}(f) + a_2 A_{i+1}
\]

(2-j) The local intersection multiplicities at the origin are given by

\[
l(C_0; C_0; O) = \Sigma_{s=1}^{i+j} a_b A_{s+1} / A_{i+1},
\]

\[
l(C_0; C_i; O) = \Sigma_{s=1}^{i+j} a_b A_{s+1} / (A_{i+1} A_{i+2}), \quad 1 \leq i < l \leq j
\]

More generally, \(l(D_a; C; O) = \Sigma_{s=1}^{\nu} A_{s+1} / (n / a) + l(D_a; C; O; \Xi),\) if \(a \mid n\) and \(a_1 \cdots a_j \mid a_j\).

(3-j) For any non-zero polynomial \(\alpha(x, y) \in C[x, y]\) with \(\deg \alpha(x, y) < a_1 \cdots a_j\), the pull back \(\Phi^*_j \alpha\) can be written as \(\Phi^*_j \alpha = U \times u^j_1\) in a small neighbourhood \(W_j\) of \(\Xi_j\) for some integer \(s > 0\).

If \(A_{j+1} = 1\), then \(h_j = f\) and (4.4.1) says that \(\Phi_j : X_j \to X_0\) is a good resolution of \(C\). If \(A_{j+1} \geq 2\), we will add to the tower a toric modification \(\Phi_{j+1} : X_{j+1} \to X_j\) keeping the above properties. Let \(P_{j+1} = (a_{j+1}, b_{j+1})\) be the weight vector of the unique face of \(\Gamma(\Phi_j^* f ; (u_j, v_j))\) characterized by (4.4.1) and (4.4.2): \(\Phi_j^* f (u_j, v_j) = u_j^{m_j(h_{j+1})} (v_j^{a_{j+1}} + \xi_j^{a_{j+1}} 1^{a_{j+1}} + \text{(higher terms)}\)

Choose a regular simplicial cone subdivision \(\Sigma_j^*\) of the \(\Gamma^* (\Phi_j^* f ; (u_j, v_j))\) and make the corresponding modification \(p_{j+1} : X_{j+1} \to X_j\) with center \(\Xi_j \in E_j\). Then \(\Phi_j^* h_{j+1}(u_j, v_j)\) is non-degenerate by (4.4.2), so in the right toric chart \(\sigma = (P_{j+1}, P_{j+1}')\) we can write \(\Phi_j^* h_{j+1}(x, y) = x_{\sigma}^{m_j(h_{j+1})} y_{\sigma}^{m_j(h_{j+1})} (y_{\sigma}^{a_{j+1}} + \xi_j^{a_{j+1}} 1^{a_{j+1}} + x_{\sigma} G)\) where \(m_{j+1}(h_{j+1})\) and \(m_{j+1}'(h_{j+1})\) are multiplicities on \(E_{j+1} = \hat{E}(P_{j+1})\) and \(E(P_{j+1}')\) respectively. The functions \(u_{j+1} = x_{\sigma}\) and \(v_{j+1} = y_{\sigma}^{a_{j+1}} (y_{\sigma}^{a_{j+1}} + \xi_j^{a_{j+1}} 1^{a_{j+1}} + x_{\sigma} G)\) give a system of coordinates in a neighborhood \(W_{j+1}\) of the intersection point \(\Xi_{j+1}\) of \(C_{j+1}^{(j+1)}\) and \(E_{j+1}\). By the definition the strict transform \(C_{j+1}^{(j+1)}\) is smooth and is defined by \(\{v_{j+1} = 0\}\) in \(W_{j+1}\). We show (3-(j+1)) first. For \(\alpha(x, y) \in C[x, y]\) with \(\deg \alpha < a_1 \cdots a_{j+1}\), its Tschirnhausen expansion with respect to \(h_j; \alpha(x, y) = \sum_{i=1}^{a_{j+1}} \alpha_i(x, y) h_j^{(j+1)}(x, y)\) has coefficients with \(\deg \alpha < a_1 \cdots a_{j+1}\). Applying inductively if \(a_i \neq 0\) we get \(\Phi_j^* (\alpha h_j^{(j+1)}) = U \times u_j^{a_{j+1}} v_j^{a_{j+1}-1} + \text{with } v_i \geq 0\) and a unit \(U_i\). So by Lemma 4.1, \(\Phi_{j+1}^* \alpha = p_{j+1}^* (\Phi_j^* \alpha) = U \times u_{j+1}^j\) for a unit \(U\) on \(W_{j+1}\) and \(s \geq 0\).

If \(a_{j+1} = A_{j+1} \) i.e., \(A_{j+2} = 1\), the modification \(\Phi_{j+1} : X_{j+1} \to X_0\) is a good
resolution of C, so clearly we have (1-(j + 1)) and (2-(j + 1)). If \( A_{j+2} \geq 2 \), we write
\[
\Phi_{j+1}^*f(u_{j+1}, v_{j+1}) = u_{j+1}^{m_{j+1}}(u_{j+1}^{m_{j+1}} + \xi_{j+2} u_{j+2}^{m_{j+2}})A_{j+2}^2 + \text{(higher terms)}
\]

Note that \( m_{j+1} - a_{j+1} = a_{j+1} + b_{j+1} + A_{j+2} \). Using the \( A_{j+2} \)-th Tschirnhausen expansions of \( f : f(x, y) = h_{j+1}^2 + c_{j+2} x h_{j+1}^2 + \ldots \), and repeating the argument in 4.3, we will prove \( \beta_{j+2} \geq 2 \).

As above, if \( c_{j+1} \neq 0 \), we write \( \Phi_{j+1}^*(c_{j+1} h_{j+1}^2) = u_{j+1}^{m_{j+1}} u_{j+1}^{m_{j+1}} \Phi_{j+1}^*(u_{j+1}^{m_{j+1}}) \) for some integer \( m_{j+1} \) and a unit \( \Phi_{j+1}^* \).

The Newton principal part \( \Phi_{j+1}^*(u_{j+1}^{m_{j+1}}) \) contains the exponent \( (m_{j+1} + b_{j+1} \beta_{j+1} - \alpha_{j+2}) \) by (4.4.4) and we conclude that \( \beta_{j+2} \geq 2 \) as in 4.3.

Now we show (1-(j + 1)). For \( a \) with \( a | n \) and \( a_1 \cdots a_{j+1} | a \), consider the Tschirnhausen expansions:
\[
f(x, y) = H_{a}^{n/a} + \sum_{i=2}^{n/a} c_i H_{a}^{n/a-i}, \quad H_a = h_{j+1}^2 + \sum_{i=2}^{\beta_{j+1} - 1} d_i h_{j+1}^{2-i}
\]
with \( \deg_c c_i < a \) and \( \deg_d d_i < a_1 \cdots a_{j+1} \) where \( \beta_{j+1} := a / a_1 \cdots a_{j+1} \). Applying the same argument to the \( h_{j+1} \)-expansion of \( R := f - H_a^{n/a} = \sum_{i=2}^{\beta_{j+1} - 1} c_i H_a^{n/a-i} \), we see:
\[
\deg_{v_{j+1}} \Phi_{j+1}^*(R) < \beta_{j+1} - 2
\]
But from (4.4.3) with \( g_{a} G_{a} \in C(u_{j+1}, v_{j+1}) \) follows:
\[
\Phi_{j+1}^* H_a^{n/a}(u_{j+1}, v_{j+1}) = u_{j+1}^{m_{j+1}}(u_{j+1}^{m_{j+1}} + \xi_{j+1} u_{j+1}^{m_{j+1}})
\]
So \( B_a := (m_{j+1}(H_a), \beta_{j+1}) \) is the left end vertex of \( \Gamma(\Phi_{j+1}^* H_a) \), \( n/a \times B_a \) is the left end vertex of \( \Gamma(\Phi_{j+1}^* H_a^{n/a}) \) and also of \( \Gamma(\Phi_{j+1}^* f : (u_{j+1}, v_{j+1})) \). By the arguments of 4.3 and (4.4.3), the first face \( \Delta_a \) of \( \Gamma(\Phi_{j+1}^* f : (u_{j+1}, v_{j+1})) \) contains \( B_a \), has the weight vector \( P_{j+1} = (a_{j+2}, b_{j+2}) \), hence
\[
(4.4.5) \quad \left\{ \begin{array}{l}
\deg_{v_{j+1}} \Phi_{j+1}^* f = \deg_{v_{j+1}} (\Phi_{j+1}^* f)_{P_{j+2}} \quad - (\Phi_{j+1}^* H_a)_{P_{j+2}}(u_{j+1}, v_{j+1}) < A_{j+2} - \beta_{j+1} \\
\deg_{u_{j+1}} ((\Phi_{j+1}^* f)_{P_{j+2}})_{u_{j+1}} = \deg_{u_{j+1}} (\Phi_{j+1}^* f)_{P_{j+2}}(u_{j+1}, v_{j+1}) < A_{j+2} - \beta_{j+1}
\end{array} \right.
\]
Note: \( \deg_{v_{j+1}} \Phi_{j+1}^* f = \deg_{v_{j+1}} (\Phi_{j+1}^* f) \). The polynomial \( H_a^{n/a}(u_{j+1}, v_{j+1}) := (\Phi_{j+1}^* H_a)_{P_{j+2}} / u_{j+1}^{m_{j+1}H_a} \) is monic in \( v_{j+1} \) of degree \( \beta_{j+1} = a / a_1 \cdots a_{j+1} \), implying with the inequality of (4.4.5) the

**Assertion 4.4.6.** If \( a_1 \cdots a_{j+1} | a \), then \( H_a^{n/a}(u_{j+1}, v_{j+1}) \) is the \( n/a \)-th Tschirnhausen approximate polynomial of \( (\Phi_{j+1}^* f)_{P_{j+2}}(u_{j+1}, v_{j+1}) / u_{j+1}^{m_{j+1}H_a} = (v_{j+1}^{m_{j+1}H_a} + \xi_{j+2} u_{j+2}^{m_{j+2}H_a})A_{j+2} \in C(u_{j+1})[v_{j+1}] \). In particular, if \( a_1 \cdots a_{j+2} | a \), then \( H_a^{n/a}(u_{j+1}, v_{j+1}) = (v_{j+1}^{m_{j+1}H_a} + \xi_{j+2} u_{j+2}^{m_{j+2}H_a})A_{j+2} \), with \( \beta_{j+2} := a / a_1 \cdots a_{j+2} \).

This proves (1-(j + 1)). The assertion about the intersection multiplicities
(2\(j + 1\)) follows immediately from Lemma 3.4.2.

As \(a_1 \cdots a_i\) divides \(n\) and \(a_i \geq 2\) for each \(i = 1, \ldots, k\), the above inductive construction stops after a finite number of toric modifications. In fact, \(k\) (respectively \(k - 1\)) is the number of Puiseux pairs if \(b_i > 1\) (resp. if \(b_i = 1\)). See [29] and [18]. Thus we have proved the following.

**Theorem 4.5.** Let \(f(x, y) \in C[x][y]\) be monic of degree \(n\) with the initial expansion
\[
f(x, y) = (y^{a_1} + \xi_1 x^{b_1})^{A_2} + \text{(higher terms)}, \quad n = a_1 A_2, \quad a_1 > 1
\]
and defining in a neighbourhood \(W_0\) an irreducible curve \(C := \{(x, y) \in W_0; f(x, y) = 0\}\) at the origin. There exists a resolution tower \(\mathcal{T}\), satisfying the following conditions\(1\) and \(2\), of toric modifications: \(\mathcal{T} = \{X_k \to X_{k-1} \to \cdots \to X_1 \to X_0 = C^2\}\) having the weight vectors \(\{P_i = (a_i, b_i); i = 1, \ldots, k\}\) where \(n = a_1 \cdots a_k, \quad a_i \geq 2, \quad i = 1, \ldots, k\). With \(A_i = a_1 a_i + a_k\), let \(h(x, y)\) be the \(A_i\)-th Tschirnhausen approximate polynomial of \(f(x, y)\) and let \(C_i = \{(x, y) \in C^2; h(x, y) = 0\}, i = 1, \ldots, k\). Note \(h_k = f\) and \(C_k = C\). Denote by \(E_i = \{p_i\}\) the center of \(p_i\) by \((u_i, v_i)\) the modification local coordinate centered at \(E_i\) so that \(\{u_i = 0\}\) is the defining equation of the divisor \(E_i\). Put \(\Phi_i = p_i \circ \cdots \circ p_i: X_i \to X_0\).

1. For each \(i = 1, \ldots, k\), \(C_i\) is an irreducible curve at the origin having the good resolution \(\Phi_i\), such that the strict transform \(C_i(0)\) in \(X_i\) is defined by \(\{v_i = 0\}\). The pull backs are
\[
\Phi_i^* h_i(u_i, v_i) = \begin{cases} u_i^{m_i(h_i)} v_i, & i = \ell \\ u_i^{m_i(h_i)} (v_i^{a_i + 1} + \xi_{i+1} u_i^{b_{i+1}})^{A_i / A_{i+1}} + \text{(higher terms)} & i < \ell \end{cases}
\]
In particular, putting \(\ell = k\),
\[
(4.5.1) \quad \Phi_i^* f(u_i, v_i) = \begin{cases} u_i^{m_i(f)} v_i, & i = k \\ u_i^{m_i(f)} (v_i^{a_i + 1} + \xi_{i+1} u_i^{b_{i+1}})^{A_i / A_{i+1}} + \text{(higher terms)} & i < k \end{cases}
\]
where the multiplicities \(m_i(h_i)\) and \(m_i(f)\) of the pull backs \(\Phi_i^* h_i\) and \(\Phi_i^* f\) on \(E_i\) satisfy the equalities: \(m_i(h_i) = m_i(f) / A_{i+1}, \quad m_1(f) = a_1 b_1 A_2\) and \(m_i(f) = a_i m_{i-1}(f) + a_i b_i A_{i+1}\) for \(i = 1, \ldots, l\). More explicitly
\[
(4.5.2) \quad \begin{cases} m_i(f) = a_1 b_i A_{i+1} + \cdots + a_i b_i A_{i+1} = (\Sigma_i A_{i+1} b_{i+1}) / A_{i+1} \\ m_i(h_i) = (\Sigma_i a_i b_i A_{i+1}^2) / (A_{i+1} A_{i+1}), \quad i \leq \ell \end{cases}
\]
2. The local intersection multiplicities are
\[
l(C_i, C_j; O) = \Sigma_{i+1} a_i b_i A_{i+1}^2 / (A_{i+1} A_{j+1}), \quad \ell < j \leq k.
\]
The equality (4.5.2) follows from (4.5.1). The other assertions are established.
in the inductive argument.

**Definition 4.5.3.** The toric tower of Theorem 4.5 is a Tschirnhausen resolution tower of toric modifications of $C$, the coordinates $(u_i, v_i)$ of $W_i$ are Tschirnhausen coordinates centered at $\Xi_i$, and the curve $C_i$ is the $A_{i+1}$-th Tschirnhausen approximate curve of $C$.

The combinatorial choice of the admissible subdivisions $\Sigma^\ast$'s determines completely the Tschirnhausen resolution tower of toric modifications. In Theorem 4.7, we will show that the length of the tower $k$ and the sequence of the weight vectors $\{P_1, \ldots, P_k\}$ are independent of the choice of a certain resolution tower of toric modifications.

**Remark 4.5.4.** Let $\alpha_i = \min(a_i, b_i)$ and $\beta_i = \max(a_i, b_i)$ and let $n_i = a_i$, $m_i = b_i$ and $n_i = a_i$, $m_i = b_i$ for $i \geq 2$. Then we have shown in Corollary 6.8 of [29] that the Puiseux pairs of $C_j$ is given by $\{(n_i, m_i); i = 1, \ldots, j\}$, $(b_1 > 1)$ or $\{(n_i, m_i); i = 2, \ldots, j\}$, $(b_1 = 1)$. The isotopy class of the knot depends only on the set of Puiseux pairs. Thus the knot given by $C_j$ at the origin can be considered as a compound torus knot along the knot given by $C_{j-1}$ for $j = 2, \ldots, k$. There exist tori in the Milnor sphere for an irreducible plane curve singularity, which are transversal to the Milnor fibration of the singularity, such that the tori give a decomposition of the complement of the knot and of the monodromy diffeomorphism of the singularity. For instance, on each piece of this decomposition the monodromy can be realized by a monodromy vector field having all its orbits closed and a surface of genus 0 as orbit space. In particular, the monodromy is in this decomposition piecewise of finite order (see [1]). More precisely, using the Tschirnhausen resolution and the modification coordinates, this decomposition of [1] is given explicitly as follows. First, the modifications $\Phi_i: X_i \to C^2$ are isomorphisms above the spheres $S_r$ of radius $r > 0$ around $0 \in C^2$. Let $(u_i, v_i)$, $1 \leq i \leq k$ be the modification coordinates of $\Xi_i \in X_i$ as in Theorem 4.5. The strict transforms $C^0_i$, $j = i, \ldots, k$ give germs of irreducible curves at $\Xi_i$ and $C^0_{\alpha}$ is given by $\{v_i = 0\}$. The sphere $S_r$ is isotopic to $|u_i| = r'$ for some $r' > 0$ in a neighborhood of $\Xi_i$. For $\varepsilon > 0$, let $T_{i, \varepsilon, r} = \{(u_i, v_i) \in S_r; |v_i| \leq \varepsilon\}$. For sufficiently small $r$ and $\varepsilon$, $T_{i, \varepsilon, r}$ is diffeomorphic to the product $K_i \times D_\varepsilon$ where $K_i := C^0_i \cap S_r$ and $D_\varepsilon := \{\eta \in C; |\eta| \leq \varepsilon\}$ and $T_{i, \varepsilon, r}$ gives a canonical tubular neighbourhood of $K_i$. We can take positive numbers $r_i, \varepsilon_i > 0$ for $i = 1, \ldots, k$ so that $C^0_j$ intersect transversely with $S_\varepsilon$ for any $\varepsilon < r_i$ and $j = i, \ldots, k$ and $C^0_j \cap S_\varepsilon \subset T_{i, \varepsilon, r}$. By the inductive argument, we can assume also that $T_{i, \varepsilon, r} \cap \partial T_{i-1, \varepsilon_i-1, r} = \emptyset$. Now taking $r_0 = \min(r_1, \ldots, r_k)$, we get

**Theorem 4.5.5.** Let $f(x, y)$ be as in Theorem 4.5. Then for every $0 < r \leq r_0$, the following properties hold.
(1) \( T_{i,i+2,r} \supset T_{i+1,i+1,r} \) for \( i = 1, \ldots, k - 1 \) where,
(2) the boundary of \( T_{i,i+1,r} \) is a torus transversal to the Milnor fibration of the singularity of \( f \),
(3) the restrictions of \( f/|f| \) to \( S_r - T_{i,i+1,r} \) and \( T_{i,i+2,r} - T_{i+1,i+1,r} \), \( i = 1, \ldots, k - 1 \) are locally trivial fibrations over the circle and
(4) the monodromy diffeomorphism of the restriction to the differences \( S_r - T_{i,i+1,r} \) and \( T_{i,i+2,r} - T_{i+1,i+1,r} \), \( i = 1, \ldots, k - 1 \) can be chosen to be of finite order.

B. Intersections of other Tschirnhausen approximate polynomials. Let, as before, \( H_a(x, y) \) be the \( n/a \)-th Tschirnhausen approximate polynomial and \( D_a = \{ H_a(x, y) = 0 \} \).

**Theorem 4.6.** If \( a | n, a_1 \cdots a_s | a \) and \( a \neq a_1 \cdots a_s \), then \( D_a \) and \( C \) have the same toric tangential direction of depth \( s \) and \( \text{I}(D_a; C; 0) = \sum_{j=1}^{s+1} a_j \beta_j A_j^{-1} / (A_{i+1} n/a) \) where \( \alpha = \min(s, \delta) \).

**Proof.** Recall that \( \Phi^* f(u, v) = u^{\beta_0/(n/a)} (v^{s+1} + \xi_{s+1} u^{s+1})^{A_s+2} + \text{(higher terms)} \). We consider the face function of the pull-back \( \Psi^* H_a \) and put \( H_a'(u, v) := (\Psi^* H_a)_{R_{s+1}}(u, v) / u^{\beta_0/(n/a)} \). We have seen in the inductive construction of the Tschirnhausen tower that \( D_a \) has the same toric tangential direction at least of depth \( s \) with \( C \). We have shown in Assertion 4.4.6 that \( H_a'(u, v) \) is the \( n/a \)-th Tschirnhausen approximate polynomial of \( (v^{s+1} + \xi_{s+1} u^{s+1})^{A_s+2} \). Now the main step of the proof is the following.

**Lemma 4.6.1.** The constant term of the polynomial \( H_a'(u, v) \in C[u_s][v_s] \) is zero and \( v^{s+1} + \xi_{s+1} u^{s+1} \) does not divide \( H_a'(u, v) \).

**Proof.** Put \( \beta_j = a / a_1 \cdots a_p \). The point is that \( \beta_{s+1} := A_{s+2} / (n/a) \) is not an integer. As \( H_a'(u, v) \) is the \( n/a \)-th Tschirnhausen approximate polynomial of \( (v^{s+1} + \xi_{s+1} u^{s+1})^{A_s+2} \), we have \( H_a'(u, v) = v^{\beta_0/(n/a)} (1 + \xi_{s+1} u^{s+1})^{A_s+2} \) by Lemma 2.3. Thus \( H_a'(u, v) \) does not have a constant term as a polynomial of \( v_s \). If \( v^{s+1} + \xi_{s+1} u^{s+1} \) divides \( H_a'(u, v) \), we will get a contradiction. In fact, the polynomial

(4.6.4) \[ H_a''(u, v) := (v^{s+1} + \xi_{s+1} u^{s+1})^{-1} H_a'(u, v) \]

is the \( n/a \)-th Tschirnhausen approximate polynomial of \( (v^{s+1} + \xi_{s+1} u^{s+1})^{A_s+2 - n/a} \). By the generalized binomial formula again, we have

\[ H_a''(u, v) = v^{\beta_0 - a_{s+1}} \sum_{j=0}^{[\beta_{s+1}] - 1} \left( \frac{\beta_{s+1} - 1}{j} \right) v^{\xi_{s+1} u^{s+1}} (v^{s+1})^j. \]

Comparing the coefficients of \( v^{\beta_0 - [\beta_{s+1}] a_{s+1}} \) in (4.6.4), we get: \( (\beta_{s+1}) = ([\beta_{s+1}] - 1) \), which
is a contradiction as $\beta_{s+1} \neq [\beta_{s+1}]$. Q.E.D.

Now by the Lemma the curve $D_a$ has the same toric tangential direction of depth $s$ but not of depth $s+1$ with $C$. In particular, $D_a^{(s+1)} \cap C^{(s+1)} = \emptyset$. The main problem in proving the assertion about the intersection multiplicity is that $D_a$ may be neither irreducible nor reduced. See Example 4.9. Let $D_{a,1}, \cdots, D_{a,\ell}$ be the irreducible components. Let $k_a(u_s, v_s)$ and $k_{a,j}(u_s, v_s)\), $j=1, \cdots, \ell$, be the defining functions of the strict transforms $D_{a}^{(s)}$ and $D_{a,j}^{(s)}$ for $j=1, \cdots, \ell$. Then we can write $k_a(u_s, v_s) = v_s^{\alpha_s} + \sum_{i=1}^{\gamma_s} \gamma_i(u_s) v_s^{-\gamma_i}$, $\gamma_i(u_s) \in \mathcal{C}\{u_s\}$ and

$$k_{a,j}(u_s, v_s) = \begin{cases} (v_s^{\alpha_{s+1}+j} + \xi_{a,j} v_s^{(s+1,j)})^{A_{s+2,j}+1}, & b_{s+1,j} \neq 0 \\ (v_s^{A_{s+2,j}} U_j, & b_{s+1,j} = 0, \ a_{s+1,j} = 1 \\
\end{cases}$$

(4.6.5)

where $\gcd(a_{s+1,j}, b_{s+1,j}) = 1$ and $U_j$ is a unit. They satisfy:

(4.6.6)

$$\beta_s = \sum_{j=1}^{\ell} a_{s+1,j} A_{s+2,j}$$

Recall that the weight vector of the unique face of $\Gamma(k_{a,j}; (u_s, v_s))$ corresponds to the weight vector of a face of $\Gamma(k_a; (u_s, v_s))$. By Assertion 4.4.6, the Newton boundary $\Gamma(k_a; (u_s, v_s))$ starts with the face (possibly a vertex) of the weight vector $P_{s+1}$ and any other face has a milder slope. Therefore we have $b_{s+1,j}/a_{s+1,j} \geq b_{s+1}/a_{s+1}$ if $b_{s+1,j} \neq 0$. Now we apply Lemma 3.4.2 to compute the intersection numbers. For $i \leq s$, we have $I(D_a, C_i) = \sum_{j=1}^{s} a_{j,j} A_{j+1}/(A_{j+1} n/a)$, $i \leq s$ and for $i \geq s$, with $P_{s+1,\ell} := (a_{s+1,\ell}, b_{s+1,\ell})$ we have

$$I(D_a, C_i) = \sum_{j=1}^{s} a_{j,j} A_{j+1}/(A_{j+1} n/a) + \sum_{t=1}^{\ell} I(P_{s+1}, P_{t,s+1}) A_{s+2,t} A_{s+2}/A_{t+1}$$

$$= \sum_{j=1}^{s} a_{j,j} A_{j+1}/(A_{j+1} n/a) + \sum_{t=1}^{\ell} b_{s+1} \beta_{s+1} A_{s+2,t} A_{s+2}/A_{t+1} \text{ by (4.6.6)}$$

$$= \sum_{j=1}^{s+1} a_{j,j} A_{j+1}/(A_{j+1} n/a), \ i > s \text{ by (4.6.5)}.$$

where $I(P_{s+1}, P_{t,s+1})$ is defined as in Lemma 3.4.2.

C. Relations with other toric towers. Consider two toric resolution towers:

$$\mathcal{F} = \{X_k^{p_k} \to X_{k-1} \to \cdots \to X_1^{p_1} \to X_0 = C^2\}$$

$$\mathcal{Q} = \{Y_s^{q_s} \to Y_{s-1} \to \cdots \to Y_1^{q_1} \to Y_0 = C^2\}$$

where $\mathcal{F}$ is a Tschirnhausen tower of resolution with the weight vectors $P_i = (a_i, b_i)$,
Let $A_i=a_1a_{i+1}\cdots a_k$ and let $h_i(x,y)$ be the $A_{i+1}$-th Tschirnhausen approximate polynomial of $f(x,y)$ and let $C_i$ be the corresponding Tschirnhausen curve for $i=1,\ldots,k$ as before. Let $Q_i=(a_i\beta_i), i=1,\ldots,s$ be the corresponding weight vectors of $\overline{\mathcal{Z}}$ with $n=a_1\ldots a_k$. We assume that $a_i \geq 2, i=1,\ldots,s$ and $Q_1=P_1$. We call such a toric tower $\overline{\mathcal{Z}}$ a Tschirnhausen-good resolution tower. A Tschirnhausen resolution tower is a Tschirnhausen-good resolution tower by Theorem 4.5. Now Theorem 4.5 can be generalized as follows.

**Theorem 4.7.** Let $f(x,y)$ be as in Theorem 4.5. Let $\mathcal{T}$ and $\overline{\mathcal{Z}}$ be as above. Assume that $q_{i+1}: Y_{i+1} \to Y_i$ is a toric modification centered at $\Theta_i \in E_i:=\mathbb{E}(Q_i)$ with the modification local coordinate system $(w_i,z_i)$, so that $\{w_i=0\}$ defines the divisor $E_i$. Put $\Psi_i=q_1\circ\cdots\circ q_i: Y_i \to Y_0$. Then we have the following properties. (1) (Uniqueness of the weight vectors) $s=k$ and $Q_i=P_i$ for $i=1,\ldots,k$. (2) For each $i=1,\ldots,s, \Psi_i: Y_i \to Y_0$ gives a good resolution of $C_i$ and the pull backs of the polynomials are written (up to a non-zero constant factor) as

\[
\Psi_i^*h_i(z_i) = \begin{cases} w_i^m(h_i)z_i^{\gamma_0} + \Theta_i w_i^{l+1}z_i^{A_i + 1} + \text{(higher terms)}, & i < \ell \\ w_i^m(h_i)z_i^\gamma, & i = \ell \end{cases}
\]

where $z_i$ is either $z_iU_i$ with a unit $U_i$ or $c_i((z_i + \eta_iw_i^{\gamma_1}) + \text{(higher terms)})$ with $c_i, \eta_i \in \mathbb{C}^*$ for some integer $\gamma_1, \gamma_i > b_{i+1}/a_{i+1}$. In particular, putting $\ell = s$, we have

\[
\Psi_i^*f(w_i,z) = \begin{cases} w_i^m(f)z_i^{\gamma_0} + \Theta_i w_i^{l+1}z_i^{A_i + 1} + \text{(higher terms)}, & i < s \\ w_i^m(f)z_i^\gamma, & i = s \end{cases}
\]

where the multiplicities $m_i(h_i)$ and $m_i(f)$ of the pull backs $\Psi_i^*h_i$ and $\Psi_i^*f$ on $E_i$ satisfy the same inductive equalities:

\[
\begin{cases} m_i(h_i) = m_i(f)/A_{i+1}, & i \leq s \\ m_i(f) = a_1b_1A_2 \quad m_i(f) = a_1m_{i-1}(f) + a_2b_iA_{i+1} \end{cases}
\]

Thus we have also the uniqueness of the multiplicities: $m_i(h_i) = m_i(h_i)$ and $m_i(f) = m_i(f)$.

**Proof.** We consider the tower $\overline{\mathcal{Z}}$. Let $\tilde{z}_i = \min(x_i,\beta_i)$ and $\tilde{\beta}_i = \max(x_i,\beta_i)$ and let $n_i = \tilde{z}_i, m_i = \tilde{\beta}_i$ and $n_i = x_i, m_i = \beta_i + \beta_{i-1}x_i + \cdots + \beta_2x_3 \cdots x_i + \tilde{\beta}_1x_2 \cdots x_i$ for $i \geq 2$. Then we have shown in Corollary 6.8 of [29] that the Puiseux pairs of $C$ is given by $\{n_i,m_i\}; i=1,\ldots,s$, $(\beta_1 > 1)$ or $\{n_i,m_i\}; i=2,\ldots,s$, $(\beta_1 = 1)$. The same assertion is true for the Tschirnhausen tower $\mathcal{T}$. By the assumption $Q_1 = P_1$ and by the uniqueness of the Puiseux pairs, we conclude that $s = k$ and $Q_i = P_i$. The expression (4.7.1) for $\ell > i$ follows easily by the induction on $i$. In fact, we know that $C_\ell$ is irreducible and $\mathcal{R}(C_\ell; C) = \Sigma_{s=1}^{\ell} a_s b_s A_{s+1} / A_{s+1}$. So by Lemma 3.4.2, $C_\ell$ can not be separated from $C$ on $Y_i, i < \ell$. Thus we have the expression
As \( \Psi_{i-1}^\ast(h_i(w_i,z_i)) \) is non-degenerate, we can write
\[
\Psi_{i}^\ast h_i(w_i,z_i) = \begin{cases} 
    c_i(z_i + \eta_i w_i^{\gamma_i}) + \text{(higher terms)}, & c_i \eta_i \in \mathbb{C}^* \\
    z_i U_i, & U_i \text{ a unit}
\end{cases}
\]
In the first case, with the formula of Theorem 4.5 we get \( I(C'^{(0)}), \Theta_0 = b_{i+1} A_{i+2} \).

So, \( \gamma_i \geq b_{i+1}/a_{i+1} \). As \( b_{i+1}/a_{i+1} \) is not an integer, we have \( \gamma_i > b_{i+1}/a_{i+1} \).

Q.E.D.

**Remark 4.8.** Theorem 4.7 can be proved without using the uniqueness of the Puiseux pairs by comparison stage by stage of the formulae for the intersections for the two towers.

**Example 4.9.** Put \( f(x,y) = (y^4 + x^3)^6 + x^{17}y^3 \). The first toric modification \( p_1 : X_1 \to X_0 \) can be defined by the subdivision
\[
\Sigma_1^\ast = \{P_{0,0}, \ldots, P_{0,5}\} = \left\{ \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \begin{pmatrix} 2 \\ 1 \end{pmatrix}, \begin{pmatrix} 3 \\ 2 \end{pmatrix}, \begin{pmatrix} 4 \\ 3 \end{pmatrix}, \begin{pmatrix} 1 \\ 1 \end{pmatrix}, \begin{pmatrix} 0 \\ 1 \end{pmatrix} \right\}
\]
with weight vector \( P_1 = P_{0,3} \). Let \( \sigma_3 = \text{Cone}(P_{0,3}, P_{0,4}) \). On the chart \( C_3^2 \), we take \( u_1 = x_3 \) and \( v_1 = y_3 + 1 \). Then \( C^{(1)} \) is defined by \( \{(u_1, v_1) \in W_1 ; v_1^6 + u_5^6 + \text{(higher terms)} = 0\} \). Thus we need one more toric modification \( p_2 : X_2 \to X_1 \) and we choose the modification with respect to
\[
\Sigma_1^\ast = \{P_{1,0}, \ldots, P_{1,7}\} = \left\{ \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \begin{pmatrix} 2 \\ 1 \end{pmatrix}, \begin{pmatrix} 3 \\ 2 \end{pmatrix}, \begin{pmatrix} 4 \\ 3 \end{pmatrix}, \begin{pmatrix} 5 \\ 4 \end{pmatrix}, \begin{pmatrix} 6 \\ 5 \end{pmatrix}, \begin{pmatrix} 1 \\ 1 \end{pmatrix}, \begin{pmatrix} 0 \\ 1 \end{pmatrix} \right\}
\]
with weight vector \( P_2 = P_{1,5} \). The weight vectors of the tower are \( P_1 = (4,3) \) and \( P_2 = (6,5) \). By computation, we have \( n = 24 \) and the various Tschirnhausen approximate polynomials are:\n\[
H_2(x,y) = y^2, \quad H_3(x,y) = y^3, \quad H_4(x,y) = h_1(x,y) = y^6 + x^3, \quad H_6(x,y) = y^6 + 3/2x^3y^2, \quad H_8(x,y) = (y^4 + x^3)^3.\n\]
The intersection multiplicities are given by \( I(D_a, C ; O) = 36, 54, 77, 108, 154, 231 \) respectively for \( a = 2, 3, 4, 6, 8, 12 \). This example shows that \( D_a \) which is different from \( C_i \), \( 1 \leq i \leq k \) is not necessarily irreducible or reduced. The zeta function and the Milnor number are given by Theorem 5.1 in §5: \( \zeta(t) = (1 - t^{72})/(1 - t^{462})/(1 - t^{24})(1 - t^{18})(1 - t^{77}) \) and \( \mu(f) = 416 \).

5. The zeta function of the monodromy. Let \( f(x,y) \) be a monic polynomial in \( y \) of degree \( n \) and irreducible at the origin. Let \( \mathcal{F} = \{X_k \to X_{k-1} \to \cdots \to X_1 \to X_0\} \) be a Tschirnhausen-good toric resolution tower with the weight vectors \( \{P_i = (a_i, b_i) ; i = 1, \ldots, k\} \). We will read off the zeta function of the monodromy and Milnor number from the data of the Tschirnhausen-good resolution tower.
Let $\Sigma^*$ be the regular simplicial cone subdivision which is used to construct the modification $p_{i+1}: X_{i+1} \to X_i$ and let $\{P_{i,0}, P_{i,1}, \ldots, P_{i,r_i}; P_{i,r_i+1}\}$ be the vertices of $\Sigma^*$ so that $P_{i,0}=(1,0)$ and $P_{i,r_i+1}=(0,1)$. Let $P_{i,j}=(a_{ij}, b_{ij})$. We assume that $p_{i+1}=P_{i,m_i}$ for $i=0, \ldots, k-1$. Note that, as $\det(P_{i,0}, P_{i,1})=\det(P_{i,r_i}; P_{i,r_i+1})=1$, $P_{i,1}$ and $P_{i,r_i}$ have the forms $P_{i,1}=(a_{i,1}, 1)$ and $P_{i,r_i}=(1, b_{i,r_i})$ respectively. This implies that $n_i<r_i$. The configuration of the exceptional divisors \{\(E(P_{i,j}); j=1, \ldots, r_i\)\} is a line configuration and $E(P_{0,0})$ is nothing but $E(P_{i,0})$. Thus the exceptional divisors of the resolution $\Phi_k:X_k \to X_0$ is the union of the strict transforms \{\(E(P_{i,j}); 0\leq i\leq k-1, 1\leq j\leq r_i\)\}. Let $m_{i,j}$ be the multiplicity of the pull-back $\Phi_{*}f$ along $E(P_{i,j})$ and let $\delta_{i,j}$ be the number of irreducible components of the divisor $(\Phi_{*}f)$ which intersect with $E(P_{i,j})$. By Theorem 3 of [2], the zeta function $\zeta(t;O)$ of the monodromy of $f(x,y)$ is determined by those $E(P_{i,j})$ with $\delta_{i,j}\neq 2$. As we have seen in §3, $m_{i,j}=d(P_{i,j}; \Phi_{*}f)$ and

$$\delta_{i,j} = \begin{cases} 3 & j=n_i \\ 1 & j=r_i, \quad i\geq 1, \quad \delta_{0,j} = \begin{cases} 3 & j=n_1 \\ 1 & j=1 \text{ or } r_1, \quad i=0 \\ 2 & \text{otherwise} \end{cases} \\ 2 & \text{otherwise} \end{cases}$$

If $n_0=1$, we subdivide $\text{Cone}(P_{0,0}, P_{0,1})$ so that we can assume that $n_0>1$. Note that $\delta_{k-1, n_{k-1}}=3$ as $E(P_{k-1, n_{k-1}})=E(P_k)$ and it intersects with $C_{(k)}$. Recall that the multiplicity $m_{i,n_i}$ is given by $m_{i,n_i}=d(P_{i+1}; \Phi_{*}f)=m_{i+1}(f)=a_{i+1}m_i(f)+a_{i+1}b_{i+1}A_{i+2}$ in the same notation as in §4. Thus we need determine $m_{0,1}$, $m_{i,r_i}$ for $i=1, \ldots, k$. To determine $m_{i,r_i}$, we consider the expression by (4.7.2): $\Phi_{*}f(u_i, v_i)=\sum_{j=1}^{r_i} (1-t^{m_i(f)})_{u_i}^{b_{i+1}}(1-t^{m_i(f)})_{v_i}^{b_{i+1}}A_{i+2}$+(higher terms) for $i<k$. As $\Sigma^*$ is assumed to be admissible for $\Phi_{*}f$, we know that $(m_i(f)+b_{i+1}A_{i+2}, 0)\in \Delta(P_{i,r_i}; \Phi_{*}f)$. This observation and the expression $P_{i,r_i}=(1, b_{i,r_i})$ implies that $m_{i,r_i}=m_i(f)+b_{i+1}A_{i+2}$ $=m_{i+1}(f)/a_{i+1}$. Finally as $(0,n)\in \Delta(P_{0,1}; f)$, we have that $m_{0,1}=A_1$ by a similar argument as above. Thus applying Theorem 2 of [2], we obtain the first part of

**Theorem 5.1.** The zeta function and Milnor number of $f(x,y)$ are:

$$\zeta(t;O)=\frac{1}{(1-t^{A_1})\prod_{i=1}^{k} (1-t^{m_i(f)})/1-t^{m_i(f)/a_i})}, \quad \mu(f;O)=1-A_1+\sum_{i=1}^{k} (A_i-1)b_iA_{i+1}$$

Proof. By the equality $-1+\mu(f;O)=\deg \zeta(t;O)$, we have

$$-1+\mu(f;O)=-A_1+\sum_{i=1}^{k} \left(1-\frac{1}{a_i}\right)m_i(f)$$

$$=-A_1+\sum_{i=1}^{k} \left(1-\frac{1}{a_i}\right)\left(\sum_{r=1}^{n_i} a_r b_r A_{r+1}^2\right)/A_{i+1}$$
Let \( f_t(x,y) = f(x,y,t) \in \mathbb{C}[x,y,t] \) be an analytic family of monic polynomial in \( \mathbb{C}[x][y] \) of degree \( n \) in \( y \) defined for \( t \) in an open connected neighborhood \( U \) of the origin in \( \mathbb{C} \). Let \( C(t) := \{ f_t(x,y) = 0 \} \), \( t \in U \), be the corresponding family of germs of curves at the origin. We assume that \( C(0) \) is irreducible and reduced at the origin and that \( f_t(x,y) \) has an initial expansion

\[
\begin{align*}
f_t(x,y) &= (y^{a_1} + \xi_1 x^{b_1})A_2 + (\text{higher terms}) \\
&= -A_1 + \sum_{\ell=1}^{k} a_{\ell} b_{\ell} A_{\ell+1} \sum_{i=\ell}^{k} \left( 1 - \frac{1}{a_i} \right) / A_{i+1}
\end{align*}
\]

with \( \xi_1 \neq 0 \) independent of \( t \) and \( a_1 \geq 2 \). Let \( X_k \rightarrow X_{k-1} \rightarrow \cdots \rightarrow X_1 \rightarrow X_0 = \mathbb{C}^2 \) be the Tschirnhausen approximate resolution tower of \( (C(0),O) \) with the weight vectors \( \{ P_i = (a_i, b_i); \; i = 1, \ldots, k \} \). We assume further that the \( A_{i+1} \)-th Tschirnhausen approximate polynomials \( h_{i}(x,y) \) of \( f_t(x,y) \) for \( i = 1, \ldots, k-1 \) are independent of the parameter \( t \). Note that this is the case if the coefficients of \( y^j \) do not depend on \( t \) for any \( j \geq n - a_1 \cdots a_{k-1} \). Consider the germs of curves \( C_i := \{ h_i(x,y) := h_{i}(x,y,t) = 0 \}, \; i = 1, \ldots, k-1 \). Finally we assume that the local intersection multiplicities satisfy the inequalities:

\[
\begin{align*}
a_k I(C_k - C_{k-1}, C(t); O) &\leq I(C(0), C(s); O) < + \infty, \quad \text{for any } t, s, \text{ with } s \neq 0.
\end{align*}
\]

**Theorem 6.2.** Under the above assumptions for the family \( f_t(x,y) \), the germs \( C(t), t \in U \), are irreducible at the origin and have the same toric tangential direction of depth \( k' \), \( k' \geq k - 1 \). The family of germs of plane curves \( \{ C(t); t \in U \} \) is an equi-singular family and \( \Phi_k : X_k \rightarrow X_0 \) gives a simultaneous resolution for the family \( \{ C(t); t \in U \} \) where \( \Phi_k = p_1 \circ \cdots \circ p_k \). In particular, the Milnor number \( \mu(f; O) \) is constant and coincides with \( \mu(f_0; O) \). Moreover, if equality holds in \( a_k I(C_{k-1}, C(t); O) \leq I(C(0), C(s); O) \) for any \( t, s \), with \( s \neq 0 \), the germs \( C(t), t \in U \) do not have the same toric tangential direction of depth \( k \).

**Proof.** We fix \( \tau \neq 0, \; \tau \in U \). We first assume that \( C(\tau) \) is irreducible. The irreducibility will be proved later. Assume that \( C(\tau) \) has the same toric tangential direction with \( C(0) \) of depth \( 0, \; 0 \leq k \). Then we can write \( C^0(\tau) \) as

\[
\{ C^0(\tau) = \{(u_j,v_j) \in W_j; f^0_j(u_j,v_j) = 0 \}
\]

\[
f^0_j(u_j,v_j) = (v_j^{a_j+1} + \xi_j^{+1} u_j^{b_j+1})A_j + (\text{higher terms})
\]

\[
=-A_1 + \sum_{\ell=1}^{k} a_{\ell} b_{\ell} A_{\ell+1} \sum_{i=\ell}^{k} \left( 1 - \frac{1}{a_i} \right) / A_{i+1}
\]

Q.E.D.

**6. Conditions implying equi-singularity.**
where \( A_j := a_j + 1 \cdots a_{j+1} A_{j+2} \) for \( j \leq 0 \). Let \( P_{\theta+1} := (a_{\theta+1}, b_{\theta+1}) \). \( P_{\theta+1} \) is a primitive weight vector and if \( P_{\theta+1} = P_{\theta+1} \), we must have \( \xi_{\theta+1} \neq \xi_{\theta+1} \) by the assumption. Comparing (6.1.1) and (6.2.1) and by the assumption, we have \( \xi_j = \xi_{\theta+1} \), \( a_j = a_{\theta+1} \), \( b_j = b_{\theta+1} \) and \( A_j = A_{\theta+1} \) for \( j \leq 0 \). Assume first that \( \theta \leq k - 1 \). By Lemma 3.4.2, the local intersection multiplicity is given by

\[
I(C(\tau), C(0); O) = \sum_{i=1}^{\theta} a_i b_i A_{i+1}^2 + 2 b_{\theta+1} A_{\theta+2} A_{\theta+2}^2
\]

where equality holds if and only if \( a_{\theta+1} + b_{\theta+1} \leq a_{\theta+1} b_{\theta+1} \) or \( b_{\theta+1} = 0 \). On the other hand, by Theorem 4.5 we have the equality: \( a_k I(C_{k-1}, C(0); O) = \Sigma_{i=1}^{k} a_i b_i A_{i+1}^2 \). Thus (6.2.2) and the assumption (6.1.2) implies that we must have \( \theta = k - 1 \) and \( a_k b_k \leq a_k b_k^2 \) or \( b_k = 0 \) and \( I(C(\tau), C(0); O) = \Sigma_{i=1}^{k} a_i b_i A_{i+1}^2 \). We assert furthermore

\[
b_k^2 \neq 0, \quad a_k b_k = a_k b_k^2.
\]

In fact, assume first that \( b_k^2 = 0 \). Then \( C(\tau) = a_k C_{k-1} \) and \( C(\tau) \) is not reduced. This is a contradiction to the assumption \( \text{dim} C[x, y]/(f_\tau, h_{k-1}) < \infty \). Assume that \( b_k^2 \neq 0 \) and \( a_k b_k \leq a_k b_k^2 \). Then we get a contradiction:

\[
a_k I(C(\tau), C_{k-1}; O) = \sum_{i=1}^{k-1} a_i b_i A_{i+1}^2 + a_k I(C_{k-1}^{k-1}, C_{k-1}^{k-1})(\tau; O)
\]

\[
= \sum_{i=1}^{k-1} a_i b_i A_{i+1}^2 + a_k b_k A_{k+1}^2
\]

\[
> \sum_{i=1}^{k-1} a_i b_i A_{i+1}^2 + a_k b_k A_{k+1}^2 = \sum_{i=1}^{k} a_i b_i A_{i+1}^2 = I(C(\tau), O; O).
\]

Thus we have proved (6.2.3). As \( \gcd(a_k, b_k) = \gcd(a_k, b_k^2) = 1 \), (6.2.3) implies \( P_k = P_k \) and \( A_{k+1} = 1 \). This also shows that \( C^{(k)}(\tau) \) is smooth. Thus under the assumption that \( C(\tau) \) is irreducible at the origin, we have proved that \( C(\tau) \) is reduced and \( \theta \leq k - 1 \), \( P_k = P_k \). This implies that \( \mu(f_\tau; O) = \mu(f_\tau; O) \) by applying Theorem 4.5 to \( C(\tau) \). Note that \( \Phi_k: X_k \to X_0 \) gives a simultaneous resolution of the family \( \{C(\tau); \tau \in U\} \). If \( \theta = k \), the assertion is obvious and \( C^{(k)}(\tau) \) intersects with \( C^{(k)}(\tau) \) at \( \chi_k \) and therefore \( I(C(0), C(\tau); O) > \Sigma_{i=1}^{k} a_i b_i A_{i+1}^2 \). This implies that the strict inequality in (6.1.2) must hold.

**Irreducibility of \( C(\tau) \).** Now we prove that \( C(\tau) \) is irreducible for any \( \tau \). Fix a \( \tau \) and assume that \( C(\tau) \) has \( s \) irreducible components at the origin \( s \geq 2 \). Let \( C(\tau; 1), \ldots, C(\tau; s) \) be the irreducible components and let \( C^{(j)}(\tau; 1), \ldots, C^{(j)}(\tau; s) \) be
their strict transforms on $X_j$. We assume that $C(\tau;i)$ has the same toric tangential direction of depth $\theta_i$ with $C(0)$. Then we can write

$$
\begin{align*}
\{C^{(j)}(\tau;i) = \{(u_p,v_p)\in W_j; f^{(j)}_{\tau,i}(u_p,v_p) = 0\} \\
\{f^{(j)}_{\tau,i}(u_p,v_p) = (v^\theta_{j+1} + \xi_{i,j} + u^\theta_{j+1})^{A_{j+1} - \theta_i} + \text{(higher terms)}\}, \quad j \leq \theta_i
\end{align*}
$$

where $A_{i,j} = a_{i,j} \ldots a_{i,\theta_i+1} A_{i,\theta_i+2}$ for $j \leq \theta_i$. By the assumption, we have $a_{i,j} = a_j$, $b_{i,j} = b_j$, $\xi_{i,j} = \xi_j$ for $j \leq \theta_i$. Put $\theta_0 = \min(\theta_1, \ldots, \theta_s)$. Then $C(\tau)$ has the same toric tangential direction of depth $\theta_0$ with $C(0)$ and we can write $C^{(0)}(\tau)$ as:

$$
\begin{align*}
\{C^{(0)}(\tau) = \{(u_p,v_p)\in W_j; f^{(0)}(u_p,v_p) = 0\} \\
\{f^{(0)}(u_p,v_p) = (v^\theta_{j+1} + \xi_{i,j} + u^\theta_{j+1})^{A_{j+1} - \theta_i} + \text{(higher terms)}\}, \quad j \leq \theta_0
\end{align*}
$$

where $A'_{i,j} := a'_{i,j} \ldots a'_{i,\theta_i+1} A'_{i,\theta_i+2}$ and by the assumption, we have $a'_i = a_i$, $b'_i = b_i$, $\xi'_i = \xi_i$, $A'_{i+1} = A_{i+1}$ for $i \leq \theta_0$. Comparing the defining equations of $C^{(0)}(\tau; 1), \ldots, C^{(0)}(\tau; s)$ and $C^{(0)}(\tau)$, we must have

$$
f^{(0)}(x,y) = \sum_{i=1}^{s} f^{(0)}_{i}(x,y), \quad A_{1,i} + \cdots + A_{s,i} = A_i, \quad i \leq \theta_0
$$

As $A_{1,i} = a_{i,1} \cdots a_{i,\theta_i+1} A_{i,\theta_i+1}$ and $s \geq 2$, this implies that

$$
\theta_i \leq k - 1 \quad \text{and} \quad A_{i,\theta_i+1} < A_{i,\theta_i+1}.
$$

We use the following notations for simplicity. $\tilde{A}_{j,i} := A_{j,i}$ for $i \leq \theta_j + 1$ and $\tilde{A}_{j,i} := 0$ for $i > \theta_j + 1$. Then by (6.2.4) and (6.2.5) we get

$$
\begin{align*}
\sum_{j=1}^{s} \tilde{A}_{j,i} & = A_i, \quad i \leq \theta_0 + 1 \quad \text{and} \quad \sum_{j=1}^{s} \tilde{A}_{j,i} < A_i, \quad i > \theta_0 + 1
\end{align*}
$$

By Lemma 3.4.2, we have with $P_{j,\theta_j+1} := (a_{j,\theta_j+1}, b_{j,\theta_j+1})$ that

$$
I(C(\tau;j), C(0); O) = \sum_{i=1}^{\theta_i} a_i b_i A_{i+1} + I(P_{j,\theta_j+1}, a_{j,\theta_j+1}, b_{j,\theta_j+1}, A_{j+2} A_{j+2}) \leq \sum_{i=1}^{\theta_i} a_i b_i A_{i+1} + b_{\theta_j+1} A_{\theta_j+2} A_{\theta_j+2} = \sum_{i=1}^{\theta_i} b_i A_{i+1} \tilde{A}_{j,i}
$$

Adding these inequalities for $j = 1, \ldots, s$ and using (6.2.5), we get

$$
I(C(\tau), C(0); O) \leq \sum_{i=1}^{k} b_i A_{i+1} \sum_{j=1}^{s} \tilde{A}_{j,i} \leq \sum_{i=1}^{k} b_i A_{i+1} A_i,
$$

where the right side is equal to $a_j I(C_{k-1}, C(0); O)$ by Theorem 4.5. With the assumption (6.1.2), we get $I(C(\tau), C(0); O) = \sum_{i=1}^{k} b_i A_{i+1} A_i$, which is equivalent to
the following two equalities:

\[(6.2.7) \quad \delta(C(\tau; f), C(0); O) = \sum_{i=1}^{k} b_i A_{i+1} \overline{A}, \quad j=1, \ldots, s\]

\[(6.2.8) \quad \sum_{j=1}^{s} \overline{A}_{j,i} = A_i, \quad i=1, \ldots, k\]

By (6.2.6) and (6.2.5), (6.2.8) is equivalent to \(\theta = k-l\). Therefore (6.2) and (6.2.8) holds if only if \(\theta = k-l\) for \(i=1, \ldots, s\) and \(a_k b_{j,k} \geq a_{j,k} b_k\). But, assuming that \(a_k b_{j,k} \geq a_{j,k} b_k\) for some \(j_0\), we obtain the inequality:

\[ a_k \delta(C_{k-1}, C(\tau); O) = \sum_{i=1}^{k-1} b_i A_{i+1} A_i + a_k \sum_{j=1}^{s} b_{j,k} A_{j,k} + b_{j,k} A_{j,k+1} \]

\[ > \sum_{i=1}^{k-1} b_i A_{i+1} A_i + \sum_{j=1}^{s} a_{j,k} b_k A_{j,k+1} = \sum_{i=1}^{k} b_i A_{i+1} A_i = \delta(C(0), C(\tau); O), \]

which contradicts \(a_k \delta(C_{k-1}, C(\tau); O) > \delta(C(0), C(\tau); O)\). So, we must have \(a_k b_{j,k} = a_{j,k} b_k\), \(j=1, \ldots, s\). As \(\gcd(a_k, b_k) = \gcd(a_{j,k}, b_{j,k}) = 1\), this is possible if and only if \(a_{j,k} = a_k\) and \(b_{j,k} = b_k\). Again this gives a contradiction: \(A_k = A_{1,k} + \cdots + A_{s,k} = s A_k\). This proves the irreducibility of \(C(\tau)\) and the proof of Theorem 6.2 is now completed.

7. An example of an equi-singular family. We study a typical equi-singular family \(f_t(x,y) := f(x,y) + tx^m\), where \(f(x,y)\) is a monic polynomial whose Newton diagram \(\Delta(f(x,y))\) is a triangle with the vertices \(A=(0,n), B=(b_1, A_2, 0), C=(m,0)\) with \(m > b_1 A_2\), having the initial expansion \(f(x,y) = (x^{a_1} + x^{b_1})^{A_2} + \) (higher terms), \(a_1 \geq 2\), and defining an irreducible germ of a plane curve \(C = \{f(x,y) = 0\}\) at the origin. Then the \(\alpha\)-th Tschirnhausen approximate polynomial of \(f_t(x,y)\) does not depend on \(t\) for any \(a|n\) with \(1 < a\), so we can apply the previous consideration to the family of germs \(C(t) := \{f(x,y) = 0\}\). A similar family is studied by Ephreim [7] using polar invariants. Let \(\{P_i = (a_i, b_i); i=1, \ldots, k\}\) be the weight vectors of the Tschirnhausen resolution tower. Let \(h_i\) be the \(A_{i+1}\)-th Tschirnhausen approximate polynomial of \(f(x,y)\) for \(i=1, \ldots, k-1\) and let \(C_i = \{(x,y) \in C^2; h_i(x,y) = 0\}\).

Proposition 7.1. With the above assumptions and notations, we have \(\delta(C(t), C(s); O) = nm\) for \(t \neq s\) and \(a_k \delta(C_{k-1}, C(t); O) \leq nm\) for any \(t \in C\).

Proof. For the proof of the equality, note: \(\delta(C(t), C(s); O) = \dim C \{x,y\} / (f_t, f_s)\) and therefore it is equal to \(\dim C \{x,y\} / (f_t, f_s x^m) = nm\). To prove the inequality, we first observe the Newton diagram \(\Delta(h_{k-1})\) is a subset of the triangle \(\Delta'\) whose
vertices are $A' = (0, n/a_k)$, $B' = (b_1 A_2 / a_k, 0)$, $C' = (m / a_k, 0)$. Here the Newton diagram $\Delta(h)$ of a polynomial $h(x,y) = \sum_{M=(\nu, \mu)} c_M x^\nu y^\mu$ is the convex hull of the lattice point $M$ with $c_M \neq 0$. In the case of $m = n$, the assertion follows from the Bezout theorem in $P^2$: $a_k I(C_{k-1}, C(t); O) \leq a_k C_{k-1} \cdot C(t) = n^2 = nm$, where $\mathcal{C}$ is the projective compactification of $C \subset C^2$ and the right side is the intersection number in $P^2$. In the case $m \neq n$, we need another argument. Choose a small ball $B$ centered at the origin $B$ containing no other intersection than the origin $O$. Let $f_s(x,y) = f_s(x,y) + \epsilon_1$ and $h_{k-1}(x,y) = h_{k-1}(x,y) + \epsilon_2$ and let $C(s) = \{(x,y) \in C^2; f_s(x,y) = 0\}$ and $C_{k-1} = \{(x,y) \in C^2; h_{k-1}(x,y) = 0\}$. For sufficiently small $\epsilon_1$, $\epsilon_2$ the intersection $C(s) \cap C_{k-1}$ is a subset of the torus $C^*$ and the number of the points of $C(s) \cap C_{k-1}$ in $B$ counted with multiplicity is equal to $I(C_{k-1}, C(t); O)$. The Newton diagram $\Delta := \Delta(f_s; (x,y))$ is the triangle with vertices 0, A and C. The number of intersection points $C(s) \cap C_{k-1}$ in $C^*$ is bounded by the theorem of Bernshtein ([6,30]):

$$C(s) \cdot C_{k-1} = 2 V_2(\Delta(f_s), \Delta(h_{k-1})) \leq 2 V_2(\Delta, \Delta / a_k) = 2 \text{Vol}(\Delta) / a_k = nm / a_k$$

Here $V_2(\Delta_1, \Delta_2)$ is Minkowski's mixed volume and we have used the monotone increasing property of Minkowski's mixed volume to the inclusion $\Delta(h_{k-1}) \subset \Delta / a_k$. See [6,30]. As $C(s) \cdot C_{k-1} \geq I(C_{k-1}, C(s))$, the inequality of the proposition follows.

8. The equi-singularity at infinity and the Abhyankar-Moh-Suzuki theorem. Let $F: C^2 \to C$ be a polynomial mapping of degree $n$. We say that $\tau \in C$ is a regular value at infinity if there exits a large number $R$ and a positive number $\delta$ so that the restriction $F: E_\infty(R, \delta) \to D_\delta$ is a trivial fibration where

$$D_\delta = \{\eta \in C; |\eta - \tau| \leq \delta\}, \quad E_\infty(R, \delta) = \{(x,y); F(x,y) \in D_\delta, \quad \sqrt{|x|^2 + |y|^2} > R\}$$

Let $C_t = F^{-1}(t)$ and let $\mathcal{C}_t$ be the projective compactification. The set $\mathcal{C}_t - C_t = \{\rho_1, \ldots, \rho_{\ell}\} \subset L_\infty$ does not depend on $t$. We recall the following result:

**Proposition 8.1** ([11]). A complex number $\tau$ is a regular value at infinity if and only if the family of germs of plane curves $\{(\mathcal{C}_t, \rho_t); t \in C\}$ is topologically stable at $t = \tau$ for any $i = 1, \ldots, \ell$.

We consider hereafter the simplest case that $C_0$ has one place at infinity, say at $\rho = (1; 0; 0)$. Namely assume that $\ell = 1$ and the germ $(\mathcal{C}_0, \rho)$ is irreducible. Then $F(x,y)$ is written as

$$F(x,y) = (y^{a_1} + \xi_1 x^{c_1}) A_2 + \text{(lower terms)}, \quad c_1 < a_1, \quad n = a_1 A_2$$

for some positive integers $a_1$, $c_1$ and $A_2$ with $a_1 \leq 2$. As $\mathcal{C}_0 \cap L_\infty = \{\rho\}$ and $\mathcal{C}_0$
is assumed to be locally irreducible at ρ, the polynomial \( F(x, y) \) has only one outside face and its outside face function has only one factor. See [19] or [30]. The standard affine coordinates \( u = Z/X, v = Y/X \) are centered at \( p \) and the curve \( \tilde{C}_t \) is defined by \( \{ f(u, v) = 0 \} \) where \( f(u, v) = f(u, v) - tu^n \) and \( f(u, v) = F(1/u, v/u) \times u^n \). In this simplest case, we have the initial expansion

\[
(8.1.2) \quad f(u, v) = (v^{a_1} + \xi_1 u^{b_1})^{A_2} + \text{higher terms}
\]

here \( b_1 = a_1 - c_1 \). Let \( C_t^\infty = \{(u, v) \in \mathbb{C}^2; f(u, v, t) := f(u, v) - tu^n = 0\} \). We can apply Theorem 6.2 using Proposition 7.1 to this family and we obtain:

**Theorem 8.2.** For the mapping \( F \) and the family \( \{(C_t^\infty, O); t \in C\} \) the following holds:

1. The family of germs of germs of plane curves \( \{(C_t^\infty, O); t \in C\} \) is an equi-singular family of irreducible curves and the Tschirnhausen approximate resolution tower of \( (C_t^\infty, O) \) resolves simultaneously each curve of the family \( \{(C_t^\infty, O); t \in C\} \).

2. The mapping \( F: \mathbb{C}^2 \rightarrow \mathbb{C} \) has no critical point at infinity.

Ephraim has also obtained a similar result about the equi-singularity using a different method [7]. See also Moh [21].

Before giving applications, we will need the following facts. Let \( D \subset \mathbb{P}^2 \) be a projective curve of degree \( n \) and let \( q_1, \ldots, q_v \) be the singular points of \( D \). Then by Plücker’s formula and by Mayer-Vietoris argument, the topological Euler number of \( D - \{q_1, \ldots, q_v\} \) is given by

\[
\chi(D - \{q_1, \ldots, q_v\}) = 2 - v - (n-1)(n-2) + \sum_{i=1}^{v} \mu(D; q_i).
\]

From this equality follow two equivalences. First, \( \mu(D; q_1) = (n-1)(n-2) \) if and only if the curve \( D - \{q_1\} \) is smooth and homeomorphic to the line \( C \). Second, \( \mu(D; q_1) = (n-1)(n-2) - 2g \) and \( v = 1 \) if and only if the curve \( D - \{q_1\} \) is smooth and homeomorphic to a punctured Riemann surface of genus \( g \). As a first application, we will give an elementary proof of:

**Theorem 8.3** (Abhyankar-Moh [5], Suzuki [31]). Let \( F(x, y) \) be a polynomial of two variables of degree \( n \) and assume that the plane curve \( C = \{(x, y) \in \mathbb{C}^2; F(x, y) = 0\} \) is smooth and homeomorphic to the complex line \( C \). Then there exists another polynomial \( G(x, y) \) so that \( (F, G) \) is an automorphism of \( \mathbb{C}^2 \).

**Proof.** The polynomial \( F(x, y) \) has one place at infinity, say at \( \rho = (1; 0; 0) \). To prove the theorem by the induction on \( n = \deg F(x, y) \), it is enough to show that \( c_1 = 1 \) in (8.1.1). In fact, if \( c_1 = 1 \), we apply the coordinate change \( (X, Y) = (v^{a_1} + \xi_1 X, Y) \)
and achieve \( \deg F(X - Y^{a_1})/\xi_1, Y) < n \). Therefore the assertion is proved by the induction on \( \deg F \).

Let \( C_0^\infty \) and \( \bar{C}_0 \) be as above. We have \( \mu(C_0^\infty; O) = (n-1)(n-2) \) since the smooth part of the curve \( \bar{C}_0 \) is homeomorphic to the line \( C \). Let us consider the Tschirnhausen approximate resolution tower of \((C_0^\infty, O); \mathcal{T} = \{X_k \rightarrow X_{k-1} \rightarrow \cdots \rightarrow X_1 \rightarrow X_0 = C^2\} \) and let \( P_i = (a_i, b_i), \ i = 1, \ldots, k \) be the weight vectors of the tower. Then by Theorem 5.1 and \( n = A_1 \), we have

\[
(A_1 - 1)(A_1 - 2) = \mu(C_0^\infty; O) = 1 - A_1 + \sum_{i=1}^{k} (A_i - 1)b_iA_{i+1},
\]

which leads to

(a) \[
\sum_{i=1}^{k} (A_i - 1)b_iA_{i+1} = (A_1 - 1)^2.
\]

From Theorem 4.5 and Bezout theorem, we deduce

(b) \[
\sum_{i=1}^{k} (A_i - 1)a_ib_iA_{i}^2 \leq A_1^2
\]

since \( a_i\mathcal{R}(C_{k-1}, C(0); \xi_0) = \sum_{i=1}^{k} a_ib_iA_{i+1}^2 \leq a_k\bar{C}_{k-1}; \bar{C}(0) = A_1^2 \). Now we are ready to show \( c_1 = 1 \). We follow the proof of Abhyankar-Moh, Lemma 3.1, [5]. Recall that \( c_1 = a_1 - b_1 \). For the case \( k \geq 2 \), the equality (a) reads \( (a_1 - 1)b_1 = (a_1 - 1)^2 \). Thus we get \( c_1 = a_1 - b_1 = 1 \). For the case \( k \geq 2 \), we rewrite (a) and (b) as

(c) \[
\sum_{i=2}^{k} (A_i - 1)b_iA_{i+1} = (a_1A_2 - 1)(c_1A_2 - 1)
\]

(d) \[
\sum_{i=2}^{k} a_ib_iA_{i+1}^2 \leq c_1A_1^2
\]

Thus taking the sum: \( (c) \times A_2 + (d) \times (1 - A_2) \), we obtain

\[
\sum_{i=2}^{k} b_iA_{i+1}(A_i - A_2) \geq A_2^2((a_1 - 1)(c_1 - 1) - 1) + A_2.
\]

The left side is obviously negative. The right side is negative only if \( c_1 = 1 \), which completes the proof.

**Theorem 8.4.** The weight vectors of a good toric resolution of the singularity at infinity of a smooth acyclic curve in \( C^2 \) satisfy \( b_i = a_{i-1}a_i - 1 \) for each \( i = 1, \ldots, k \), where \( a_0 = 1 \).
Proof. Substituting $c_1 = 1$ in (c) and (d), we get

\[(e) \sum_{i=3}^{k} (A_i - 1)b_i A_{i+1} = (a_2 A_3 - 1)(c_2 A_3 - 1)\]

\[(f) \sum_{i=3}^{k} a_i A_{i+1}^2 \leq c_2 A_3^2\]

where $c_i = a_{i-1}a_i - b_i$ for $i = 2, \cdots, k$. Thus again taking the sum: (e) $\times A_3$ + (f) $\times (1 - A_3)$, we obtain

$$\sum_{i=3}^{k} b_i A_{i+1}(A_i - A_3) \geq A_3\{(a_2 - 1)(c_2 - 1) - 1\}A_3 + 1\}$$

The left side is obviously negative. The right side is negative only if $c_2 = 1$. The assertion for $i \geq 2$ can be proved by an easy induction. Q.E.D.

The following example shows that all weight vectors having the property of Theorem 8.4 occur.

**Example 8.5.** Let $a_i \geq 2$, $i = 1, \cdots, k$ be given integers, and let $n = a_1 \cdots a_k$. Let us consider the sequence of automorphisms:

$$\varphi_i : \left(\begin{array}{c} x_i \\ x_{i+1} \end{array}\right) \mapsto \left(\begin{array}{c} x_{i+1} \\ x_{i+2} \end{array}\right), \quad x_{i+2} = x_i + x_{i+1}^a, \quad i = 0, \cdots, k - 1$$

where $x_0 = x$ and $x_1 = y$. Let $F(x, y) = x_{k+1}(x, y)$. Then $F(x, y)$ obviously satisfies the assumption of Theorem 8.3. Let

$$\begin{cases} h_0 = v \\ h_1(u, v) = v^{a_1} + u^{a_1} - 1 \\ h_2(u, v) = h_1(u, v)^{a_2} + h_0(u, v)u^{a_1 a_2 - 1} \\ h_i(u, v) = h_{i-1} + h_{i-2}(u, v)u^{a_1 \cdots a_{i-2}(a_{i-1} a_i - 1)} - 1, \quad 2 \leq i \leq k \end{cases}$$

and let $f(u, v) = h_k(u, v)$. Then $(\mathbb{C}^2 ; O)$ is defined by $C_0^\infty = \{(u, v) \in \mathbb{C}^2 ; f(u, v) = 0\}$. It is easy to see that $h_i$ is the $A_{i+1}$-th Tschirnhausen approximate polynomial of $f$. By an inductive argument we can prove that the weight vectors of the Tschirnhausen approximate resolution tower are given by

$$P_1 = \left(\begin{array}{c} a_1 \\ a_1 - 1 \end{array}\right), \quad P_2 = \left(\begin{array}{c} a_2 \\ a_1 a_2 - 1 \end{array}\right), \cdots, \quad P_k = \left(\begin{array}{c} a_k \\ a_k - a_1 a_k - 1 \end{array}\right)$$

and the pull-backs of the Tschirnhausen approximate polynomials to $X_i$ are given by
\[ \Phi^*_{i+1}(u_i, v_i) = u_i^{\eta_i(h_i)}v_i \]
\[ \Phi^*_{i-1}(u_i, v_i) = u_i^{\eta_i(h_{i-1})}(u_i^{\eta_i+1} + \xi_{i+1}u_i^{\eta_i+1} - 1) \]
\[ \Phi^*_{j-1}(u_j, v_j) = u_j^{\eta_j(h_j)}(u_j^{\eta_j-1} + \xi_{j+1}u_j^{\eta_j-1} - 2u_j^{\eta_j-1} - 2u_j^{\eta_j-1} - 1) \]

where \( h_i(u_i, v_i) := \Phi^*_{i}(u_i, v_i)/u_i^{\eta_i(h_i)} \) and \( \xi_{i+1} \) is a unit in a neighbourhood \( W_i \) of \( \Xi_i \). The Milnor number is equal to \( (n-1)(n-2) \) by Theorem 5.1. It is convenient to introduce the notation \( a_0 = 1 \) and \( m_0(h_i) = 0 \) to understand \( (\#_1) \) as a special cases of \( (\#_{i+1}) \).

**Remark (8.6).** Let \( F(x, y) \) be a polynomial of degree \( n \) and coefficients in a subfield \( k \) of \( C \), such that the curve \( C = \{ F(x, y) = 0 \} \subset C^2 \) is smooth and contractible. Then the completion of \( C \) requires one extra point \( \rho \) at infinity having its coordinates in \( k \). So, after a linear change of coordinates defined over \( k \), the pencil \( L_t = \{ y = t \} \), computed in the affine line \( L_t \), of the points of the intersection \( L_t \cap C \), weighted by the multiplicity. The automorphism \( (x, y) \to (x - B(y), y) \), which is defined over \( k \), moves the curve \( C \) to a curve \( C' \) of lower degree and having at infinity one Puiseux pair less. In the notation of Theorem 8.3, we can write \( B(y) = -y^{a_1}/\xi_1 + \text{(lower terms)} \). The iteration of this procedure constructs an automorphism defined over \( k \), which moves the curve \( C \) to a line. Of course, we can apply this procedure to any curve \( D = \{ G(x, y) = 0 \} \), as long as the completion of the curve \( D \) has only one irreducible singularity at infinity and \( c_1 = 1 \). After at most \( \log_2(\text{degree}(G)) \) automorphisms applied to the curve \( D \), either the curve \( D \) becomes a line and the equation linear, in which case the curve \( D \) was smooth and contractible, or the curve \( D \) becomes a curve for which \( c_1 \geq 2 \). This provides a test for the contractibility and smoothness of the curve \( D \). It is straightforward to make a fast testing procedure with the help of Maple or Mathematica.

We can apply the above remark and argument to get:

**Theorem 8.7.** Let \( C \subset C^2 \) be a smooth curve homeomorphic to a Riemann surface with one puncture of genus \( g \), \( g = 1 \) or 2. Then there exists an automorphism of \( C^2 \) moving the curve \( C \) to a smooth cubic curve which is tangent to the line at infinity with the intersection multiplicity 3 if \( g = 1 \), and to a curve of degree 5 with a cusp singularity at infinity, which is homeomorphic to \( v^5 + u^3 = 0 \), if \( g = 2 \).

Proof. Let \( \mathcal{F} = \{ X_k \to X_{k-1} \to \cdots \to X_1 \to X_0 = C^2 \} \) be a Tschirnhausen tower of resolution of the singularity at infinity with the corresponding weight vectors \( \{ P_i = (a_i, b_i) \}; i = 1, \ldots, k \} \) as before. Applying barycentric automorphisms if necessary, we can assume that \( c_1 \geq 2 \) (see Remark 8.6). The equalities (a) and (c) take the
following form.

\[ \sum_{i=1}^{k} (A_i - 1) b_i A_{i+1} = (A_1 - 1)^2 - 2g \]

\[ \sum_{i=2}^{k} (A_i - 1) b_i A_{i+1} = (a_1 A_2 - 1)(c_1 A_2 - 1) - 2g \]

The inequality (b) and (d) are valid as before. Then taking the sum:

\[ (c_g) \times A_2 + (d) \times (1 - A_2), \]

we obtain

\[ \sum_{i=2}^{k} b_i A_{i+1} (A_i - 2) \geq A_2^2 ((a_1 - 1)(c_1 - 1) - (2g - 1) A_2. \]

Note also that \( a_1 \geq 3 \) by the assumption \( c_1 \geq 2. \)

(1) Assume first \( k = 1. \) Then we have \((a_1 - 1)(c_1 - 1) = 2g. \) So, for the natural number \( c_1 := a_1 - b_1 \) we have \( a_1 > c_1 = 1 + 2g / (a_1 - 1). \) We conclude that \( a_1 = 3, \) if \( g = 1 \) and that \( a_1 = 5, \) if \( g = 2. \)

So, for \( g = 1, \) we have \( a_1 = 3, \) \( c_1 = 2. \) As \( b_1 = 1, \) the curve \( C \) has no singularity at infinity but \( C \) is tangent to the line at infinity with the tangent multiplicity 3. An example of such curve is given by \( C = \{ y^3 + x^2 + 1 = 0 \}. \) For \( g = 2 \) we have \( a_1 = 5 \) and \( c_1 = 2. \) An example of such curve is given by \( C = \{ y^5 + x^2 + 1 = 0 \}. \) The curve \( C \) has a non-degenerate cusp singularity at infinity.

(2) Now we show the case \( k \geq 2 \) does not occur. With \( a_1 > c_1 \geq 2, \) we deduce from the inequalities (\( e_g \)):

\[ A_2 \leq \frac{2g - 1}{((a_1 - 1)(c_1 - 1) - 1)} \leq (2g - 1) \]

If \( g = 1, \) we get, from (*) \( A_2 = 1, \) and hence \( k = 1. \)

If \( g = 2, \) we reduce from (*) \( A_2 \leq 3 \) that \( A_2 = 1, 2 \) or 3. We first rule out the case \( A_2 = 3; \) indeed, from (*) we conclude \( k = 2, a_1 = 3, c_1 = 2, b_1 = 1. \) So, \( a_2 = A_2 = 3, n = 9 \) and \( b_2 = 18 \) by \( (a_g). \) This is not possible since we have assumed \( \gcd(a_2,b_2) = 1. \)

Next, we rule out the case \( A_2 = 2: \) from (*), we conclude \( k = 2, a_1 = 3, c_1 = 2, b_1 = 1. \) So, \( a_2 = A_2 = 2, n = 6, b_1 = 1 \) and \( b_2 = 11 \) by \( (a_g). \) Thus the tower has the weight vectors \( P_1 = (3,1) \) and \( P_2 = (2,11). \) No easy contradiction yet. However we assert that there is no polynomial \( f(u,v) \) of degree 6, irreducible at the origin, whose weight vectors are as above. Indeed, let \( f(u,v) = (v^3 + u)^2 + \Sigma v c_i u^{v_1} v^{v_2} \) where \( 6 < 3v_1 + v_2, \) \( v_1 + v_2 \leq 6. \) Consider an admissible toric modification \( p: X_1 \to C^2. \) We may assume that \( \sigma = \text{Cone}(E_1, P_1) \) is the left toric cone of the divisor \( L(P_1) \) and let \((s,t)\) be the toric coordinates. Then we have \( u = st^3 \) and \( v = t. \) The pull backs can be written as \( \pi_\sigma^*(v^3 + u)^2 = t^6(1 + s)^2 \) and \( \pi_\sigma^* u^{v_1} v^{v_2} = s^v t^{3v_1 + v_2}. \) So, in \( t^{-6} \pi_\sigma^* f(s,t) \)
the monomial $t^{11}$ does not occur and hence $P_2$ is not the second weight vector for $f(u,v)$. Thus this case does not occur. So $A_2 = 1$ proving $k = 1$. Q.E.D.

**Remark (8.9).** Using (*) and the inequality: $2^{k-1} \leq A_2$, we get the following estimate for the length of the tower:

$$k \leq \log_2(2g-1) + 1, \quad \text{for} \quad g \geq 1, \quad c_1 \geq 2.$$ 

The classification for $g \geq 3$ is more complicated, as the model is not unique. For example, in the case of $g = 3$, we can move $C$ by an automorphism to one of the following.

(a) $k = 1$, $P_1 = (4,1)$ and $n = 4$. The curve is smooth at infinity and tangent to the line at infinity at a single point. An example is given by $y^4 + x^3 + 1 = 0$.

(b) $k = 1$, $P_1 = (7,5)$ and $n = 7$. The curve has a non-degenerate cusp singularity at infinity. An example is given by $y^7 + x^2 + 1 = 0$.

(c) $k = 2$, $P_1 = (3,1)$, $P_2 = (2,9)$ and $n = 6$. An example is given by $(y^3 + x^2)^2 + x$.

We thank Professor Walter Neumann for communicating to us the reference of his earlier work [23], in which he obtained the classification of smooth affine curves with one place at infinity for $g \leq 4$. Professor M. Miyanishi recently communicated to us that he gave a new proof of Theorem 8.3 using the classification of surfaces [9]. Also, the paper [34] contains interesting results about contractible affine curves with one isolated singularity.
