# CONTRIBUTION TO THE THEORY 

OF

## EXTREME STATISTIC AND ORDER STATISTICS

AUGUST 1986

BY

RINYA TAKAHASHI

## SUMMARY

This thesis is concerned with the theory of extreme statistic and order statistics, including applications of the latter in some fields of statistical inference.

In Chapter 1, an asymptotic theory of univariate extreme statistic was treated. Properties of tail equivalence and extreme value distributions were investigated. Simple sufficient conditions for the domain of attraction of the double exponential distribution and analytic expressions of the normalizing constants were given. A number of examples to illustrate the results were shown.

In Chapter 2, an asymptotic theory of multivariate extreme statistic was treated. Basic properties of multivariate extreme value distributions were proved. Characterizations of multivariate extreme value distribution by its marginal independence were shown. Also, multivariate extensions of the results on univariate tail equivalence and extreme value distributions were established.

In Chapter 3, an application of the distribution theory of order statistics was considered. It was proved that the family of Weibull distributions with varying shape parameter is outlier-prone completely. Properties of tails of outlier-prone and outlier-resistant distributions were established. Relations between the properties of outliers and the types of extreme value distributions were shown.

Finally in Chapter 4, an application of the order statistics to statistical inference was dealt with. In the time truncated life testing problem, a sequential procedure was proposed and its properties were investigated. In the non-regular estimation problem, the second order efficiency of the maximum probability estimators was introduced and discussed.

## CHAPTER 0

## INTRODUCTION

Extreme statistic and order statistics have been studied by many authors, because they play an important role in statistical theory. In this thesis, properties of univariate and multivariate extreme statistic and applications of order statistics were studied.

In Chapter 1 we dealt with an univariate extreme statistic. Let $X_{1}, X_{2}$, ... be a sequence of independent random variables with common distribution function $F$ and then define the extreme statistic $Z_{n}=\max \left(X_{1}, X_{2}, \cdots, X_{n}\right)$. If there exist sequences of constants $a_{n}>0$ and $b_{n}$ for which $\left(Z_{n}-b_{n}\right) / a_{n}$ has a nondegenerate limit distribution $H$, then $F$ is said to be in the domain of attraction of $H$ and $H$ is said to be an extreme value distribution.

Fisher and Tippett [5] have established that a distribution function with non empty domain of attraction is of one of the following three types:

$$
\begin{aligned}
& \Phi_{\alpha}(x)=\left\{\begin{array}{cl}
0 & \text { if } x \leq 0, \\
\exp \left(-x^{-\alpha}\right) & \text { if } x>0,
\end{array}\right. \\
& \Psi_{\alpha}(x)=\left\{\begin{array}{cc}
\exp \left(-(-x)^{\alpha}\right) & \text { if } x<0, \\
1 & \text { if } x \geq 0,
\end{array}\right. \\
& \Lambda(x)=\exp \left(-e^{-x}\right), \quad-\infty<x<\infty,
\end{aligned}
$$

where $\alpha$ is a positive constant. Sufficient conditions for the domain of attraction of the limit distributions were given by Mises [15]. Gnedenko [8] has established necessary and sufficient conditions for the domain of attraction of $\Phi_{\alpha}, \Psi_{\alpha}$ and .. Gnedenko points out, however, that he has not found satisfactory results in the case of 1 . Haan [12] has established other necessary and sufficient conditions for the domain of attraction of $\Lambda$. Gnedenko's results were generalized by Smirnov [22]. Resnick [19] has
established the results on tail equivalence and asymptotic distribution of extreme statistic.

In Section 1.2 we considered the normalizing constants of distribution functions which belong to the domain of attraction of $\Psi_{\alpha}$, and extended the results of Resnick [19].. This section is based on Takahashi [23]. In Section 1.3 we considered the domain of attraction of $\Lambda$. We showed some properties of normalizing constants. Simple sufficient conditions that a distribution function belongs to the domain of attraction of $\Lambda$, and expressions of the normalizing constants were given. In Section 1.4, a number of examples to illustrate the results of Section 1.3 were shown. Sections 1.3 and 1.4 are based on Takahashi $[24,28]$.

In Chapter 2 we dealt with a multivariate extreme statistic. Let $\mathbf{X}^{(1)}$, $x^{(2)}, \ldots$ be a sequence of independent $k$-dimensional random vectors with common distribution function $F$ and let

$$
Z_{i}^{(n)}=\max _{1 \leq j \leq n} X_{i}^{(j)}, i=1, \cdots, k
$$

If there exist vectors $\mathbf{a}^{(n)}$ and $\mathbf{b}^{(n)}$ in $\mathbf{R}^{k}$ for which $\left(\mathbf{z}^{(n)}-\mathbf{b}^{(n)}\right) / \mathbf{a}^{(n)}$ has a nondegenerate limit distribution $H$, then $F$ is said to be in the domain of attraction of $H$ and $H$ is said to be a multivariate extreme value distribution. Results for the multivariate extreme value distributions, obtained by Sibuya [20], Nair [16], Galambos [6] and others, have been summarized by Galambos [7]. Recently, Marshall and Olkin [14] have established a multivariate analogs of Gnedenko's necessary and sufficient conditions for the domain of attraction.

In Section 2.2 we proved the basic properties of multivariate extreme value distributions. Next we characterized the multivariate extreme value distribution by its marginal independence. The content in this section is due to Takahashi $[27,30]$. In Section 2.3 we established multivariate
extensions of the results of Resnick [19] on tail equivalence and asymptotic distributions of extremes. This section is based on Takahashi [27]. Some examples were shown in Section 2.4.

In Chapter 3 we dealt with an application of order statistics. Using the order statistics, Neyman and Scott [17] considered the ideas of outlier-proneness and outlier-resistance of a family of distributions and showed that the family of gamma distributions and the family of lognormal distributions are outlier-prone completely. On the other hand, Green [10] considered the ideas of outlier-proneness and outlier-resistance of individual distributions and gave theorems concerning necessary and sufficient conditions for outlier-proneness and outlier-resistance of distributions.

In Section 3.2, using the same device of Neyman and Scott [17], we showed the family of Weibull distributions with varying shape parameter is outlier-prone completly. In Sections 3.3 and 3.4 , we considered the outlierprone and outlier-resistant distributions introduced by Green [10] proved some properties of tails of outlier-prone and outlier-resistant distributions. Next we showed the relations between the properties of outlier and the types of extreme value distributions. The contents of this chapter is due to Takahashi [29].

Finally in Chapter 4 we dealt with the problems of statistical inference, using the order statistics. Padgett and Wai [18] considered the following life test. Let $n$ independent items with life distribution $F_{\theta}$ be put on life test at the outset, and suppose items are not replaced upon failure. It is assumed that $F_{\theta}$ is stachastically increasing in $\theta$. They considered the hypotheses $H_{0}: \theta \geq \theta_{0}$ versus $H_{1}: \theta \leq \theta_{1}\left(\theta_{1}<\theta_{0}\right)$ and proposed a one-sided sequential test based on $X_{n}(t)$, the number of failed items before or at time $t \leq t_{0}$, where $t_{0}$ is a specified truncation time for the test. They derived the average sampling time, and developed an
interval estimation procedure for $\theta$ after acceptance of $H_{0}$.
In Section 4.2 we improved and extended the results on the sequential test proposed by Padgett and Wei [18], and derived the average sampling time (see Takahashi [25]). In Section 4.3, another sequential test procedure based on $X_{n}(t)$ was proposed and analyzed its properties. This procedure allows a quick acceptance of $H_{0}$ when $H_{0}$ is true (see Takahashi [26]). Weiss and Wolfowitz [31] developed a theory of maximum probability estimators and applied it to some non-regular estimation problems in which a function of extreme statistic is the muximum probability estimator.

In Section 4.4 we introduced the notion of the second order efficiency which we apply to some non-regular estimation problems (see Takahashi [23]).

In this thesis we have used the following results of analysis and probability theory. Proofs and further details can be found in Haan [12].

DEFINITION 0.1. Let $\mathbf{R}^{+}$be the set of positive real numbers. $A$ function $R: \mathbf{R}^{+} \rightarrow \mathbf{R}^{+}$varies regularly at infinity if there exists a $\rho \varepsilon \mathbf{R}$ such that for all $x \in \mathbf{R}^{+}$

$$
\lim _{t \rightarrow \infty} R(t x) / R(t)=x^{\rho}
$$

This number $\rho$ is called the exponent of regular variation. In the particular case $\rho=0, R$ is often called slowly varying at infinity. For brevity we also say that $R$ is $\rho$-varying at infinity.

THEOREM 0.1. (a) If a function $R: \mathbf{R}^{+}+\mathbf{R}^{+}$is Lebesgue-integrable on finite intervals and regularly varying with exponent $\rho$, then there exist functions $a: \mathbf{R}^{+} \rightarrow \mathbf{R}$ and $c: \mathbf{R}^{+} \rightarrow \mathbf{R}^{+}$with
$\lim c(x)=c_{0}\left(0<c_{0}<\infty\right), \quad \lim a(x)=\rho$, $x+\infty \quad x \rightarrow \infty$
such that

$$
R(x)=c(x) \exp \left\{\int_{1}^{x} \frac{a(t)}{t} d t\right\} \quad \text { for all positive } x
$$

(b) If $R$ is $\rho$-varying at infinity $(-\infty<\rho<\infty)$, then for all sequences $\left\{a_{n}\right\}$ and $\left\{a_{n}^{\prime}\right\}$ of positive numbers with

$$
\begin{aligned}
& \lim _{n \rightarrow \infty} a_{n}=\lim _{n \rightarrow \infty} a_{n}^{\prime}=\infty \quad \text { and } \\
& \lim _{n \rightarrow \infty} a_{n} / a_{n}^{\prime}=c \quad(0<c<\infty),
\end{aligned}
$$

we have

$$
\lim _{n \rightarrow \infty} R\left(a_{n}\right) / R\left(a_{n}^{\prime}\right)=c^{\rho}
$$

(c) Suppose $R_{1}$ and $R_{2}$ are non-increasing and $\rho$-varying at infinity $(-\infty<\rho<0)$. For $0 \leq c \leq \infty$ we have

$$
\lim _{x \rightarrow \infty} R_{1}(x) / R_{2}(x)=c
$$

if and only if

$$
\lim _{x \rightarrow \infty} R_{1}^{*}(x) / R_{2}^{*}(x)=c^{-1 / \rho}
$$

where $R_{i}^{*}(x)=\inf \left\{y: R_{i}(y) \leq 1 / x\right\}, i=1,2$.

LEMMA 0.1. Suppose that for positive functions $f$ and $g$ on $\mathbf{R}$ both

$$
\int_{0}^{\infty} f(t) d t \quad \text { and } \quad \int_{0}^{\infty} g(t) d t
$$

are finite and

$$
\lim _{t \rightarrow \infty} f(t) / g(t)=c \quad \text { with } \quad 0 \leq c \leq \infty .
$$

Then

$$
\lim _{t \rightarrow \infty} \frac{\int_{t}^{\infty} f(s) d s}{\int_{t}^{\infty} g(s) d s}=c
$$

THEOREM 0.2. Suppose that the distribution function $H$ is continuous on the whole real line and strictly increasing on $\{x: 0<H(x)<1\}$. Suppose for a sequence $\left\{F_{n}\right\}$ of distribution functions there exist $a_{n}>0$ and $b_{n}, n=1,2, \cdots$ such that

$$
F_{n}\left(a_{n} x+b_{n}\right) \rightarrow H(x)
$$

Let $\left\{\alpha_{n}\right\}$ and $\left\{\beta_{n}\right\}$ be sequences of positive numbers tending for $n \rightarrow \infty$ to limits $\alpha$ and $\beta$ respectively, where $0<\alpha<\beta<1$. If we define

$$
\begin{array}{ll}
B_{n}=\xi_{\alpha_{n}}^{(n)}, & B=H^{-1}(\alpha), \\
A_{n}=\xi_{\beta_{n}}^{(n)}-B_{n}, & A=H^{-1}(\beta)-B,
\end{array}
$$

where ${\underset{\gamma}{(n)}}_{(n)} \inf \left\{x: F_{n}(x) \geq \gamma\right\}$, then we have

$$
F_{n}\left(A_{n} x+B_{n}\right) \rightarrow H(A x+B)
$$

LEMMA 0.2. Let $U$ and $V$ be two distribution functions neither of which is concentrated at one point. If for a sequence $\left\{F_{n}\right\}$ of distribution functions and constants $a_{n}>0, \alpha_{n}>0, b_{n}$ and $\beta_{n}$

$$
\begin{equation*}
F_{n}\left(a_{n} x+b_{n}\right)+U(x), \quad F_{n}\left(a_{n} x+\beta_{n}\right)+V(x) \tag{0.1}
\end{equation*}
$$

then
and
(0.3)

$$
\begin{equation*}
\lim _{n \rightarrow \infty} \alpha_{n} / a_{n}=A>0, \quad \lim _{n \rightarrow \infty}\left(B_{n}-b_{n}\right) / a_{n}=B \tag{0.2}
\end{equation*}
$$

$$
V(x)=U(A x+B)
$$

is true. Conversely, if (0.2) holds then each of the two relations (0.1) implies the other and (0.3).

## CHAPTER 1

## ASYMPTOTIC THEORY OF EXTREME STATISTIC - UNIVARIATE CASE

### 1.1. Introduction

In this chapter we deal with the univariate extreme statistic. We extend the results of Resnick [19] (see Theorem 1.7), and give simple sufficient conditions for a distribution function to belong to the domain of attraction of $\Lambda$ and a method to determine the normalizing constants.

Let $X_{1}, X_{2}, \cdots, X_{n}$ be a sequence of independent random variables with common distribution function $F$ and let

$$
Z_{n}=\max _{1 \leq i \leq n} X_{i}
$$

If there exist sequences of constants $a_{n}>0$ and $b_{n}$ such that $\left(Z_{n}-b_{n}\right) / a_{n}$ has a nondegenerate limit distribution $H$, or $F^{n}\left(a_{n} x+b_{n}\right)+H(x)$, then $F$ is said to be in the domain of attraction of $H$ (notation $F \varepsilon \mathbf{D}(H)$ ), $H$ is said to be an extreme value distribution, and $a_{n}$ and $b_{n}$ are called normalizing constants.

In the sequel we use the following notations

$$
x_{F}^{0}=\sup \{x: F(x)<1\}
$$

and

$$
\bar{F}^{-1}(p)=\inf \{x: 1-F(x) \leq p\}, \quad 0<p<1
$$

Note that $x_{F}^{0} \leq \infty$. The number $x_{F}^{0}$ is called the endpoint of the distribution function $F$.

Now we summarize some univariate results which are used in this thesis.

Gnedenko [8] showed the following classical results of necessary and sufficient conditions for a distribution function to belong to the domain of attraction of extreme value distributions.

LEMMA 1.1. Suppose $\left\{a_{n}\right\}$ and $\left\{b_{n}\right\}$ are sequences of real numbers and $a_{n}>0$ for $n=1,2, \cdots$. For distribution functions $F$ and $H$ we have for a fixed real $x$ with $0<H(x)<1$

$$
\lim _{n \rightarrow \infty} F^{n}\left(a_{n} x+b_{n}\right)=H(x)
$$

if and only if

$$
\lim _{n \rightarrow \infty} n\left\{1-F\left(a_{n} x+b_{n}\right)\right\}=-\log H(x)
$$

THEOREM 1.1. A distribution function $F$ belongs to $D\left(\Phi_{\alpha}\right)$ if and only if $1-F$ is $-\alpha$-varying at infinity. Moreover

$$
F^{n}\left(a_{n} x\right)+\Phi_{\alpha}(x)
$$

holds with $a_{n}=\bar{F}^{-1}(1 / n), n=1,2, \cdots$.

THEOREM 1.2. A distribution function $F$ belongs to $D\left(\Psi_{\alpha}\right)$ if and only if $F$ has a finite endpoint $x^{0}$ and the function $R$ defined by $R(x)=$ 1-F( $\left.x^{0}-1 / x\right)$ for all $x>0$ is - $\alpha$-varying at infinity. Moreover

$$
F^{n}\left(a_{n} x+x^{0}\right)+\psi_{\alpha}(x)
$$

holds with $a_{n}=\left\{x^{0}-\bar{F}^{-1}(1 / n)\right\}^{-1}, n=1,2, \cdots$.

Now we quote the following theorems concerning the domain of attraction of $\Lambda$.

THEOREM 1.3. (Necessary and sufficient conditions.) For a distribution function $F$, let

$$
\begin{aligned}
& b(s)=\bar{F}^{-1}(1 / s), \\
& a(s)=b(e s)-b(s)
\end{aligned}
$$

and

$$
x^{0}=x_{F}^{0} .
$$

Then the following assertions are equivalent.
(a) $F \in \mathrm{D}(\Lambda)$.
(b) (Gnedenko [8] and Haan [12]) There exist $a_{n}>0, b_{n}, n=1,2, \ldots$ such that

$$
F^{n}\left(a_{n} x+b_{n}\right) \rightarrow \Lambda(x) .
$$

Moreover, we can take $b_{n}=b(n), a_{n}=a(n)$ or $f_{a}\left(b_{n}\right)$, where $f_{a}$ is the auxiliary function of $F$ (see (c)).
(c) (Gnedenko [8] and Haan [12]) There exists a function $f_{a}: \mathbf{R} \rightarrow \mathbf{R}^{+}$such that

$$
\lim _{t+x^{0}} \frac{1-F\left(t+x \cdot f_{a}(t)\right)}{1-F(t)}=e^{-x} \quad \text { for all } x \varepsilon \mathbf{R} .
$$

Moreover, we can take

$$
f_{a}(t)=\frac{\int_{t}^{x^{0}}\{1-F(s)\} d s}{1-F(t)} \quad \text { for all } t<x^{0} .
$$

Such a $f_{a}$ is said to be an auxiliary function of $F$.
(d) (Mejzler, see Haan [12]) For every positive $x$ and $y(y \neq 1)$

$$
\lim _{s \rightarrow \infty} \frac{b(s x)-b(s)}{b(s y)-b(s)}=\frac{\log x}{\log y}
$$

(e) (Haan [12]) There exist functions $\alpha: \mathbf{R} \rightarrow \mathbf{R}^{+}$and $\mathrm{B}: \mathbf{R} \rightarrow \mathbf{R}$, such that

$$
\lim _{s \rightarrow \infty} s\{1-F(\alpha(s) x+\beta(s))\}=e^{-x} \quad \text { for all } x \varepsilon \mathbf{R} .
$$

Moreover, we can take $\alpha(s)=a(s)$ and $\beta(s)=b(s)$.

THEOREM 1.4. (Sufficient conditions.) If one of the following conditions holds, then we have $F \varepsilon \mathrm{D}(\Lambda)$.
(a) (Mises [15]) The endpoint of $F$ is infinite, $F$ is twice differentiable at least for all $x$ greater than some value $x_{0}$, and is such that

$$
\lim _{x \rightarrow \infty} \frac{d}{d x}\left[\frac{1-F(x)}{F^{\prime}(x)}\right]=0,
$$

where the prime denoting the derivative.
(b) (Haan [12]) There exists a distribution function $G \in D(\Lambda)$ such that the function $R: \mathbf{R}^{+}+\mathbf{R}^{+}$defined by $R(x)=[1-F(x)] /[1-G(x)]$ is regularly varying at infinity.
(c) (Haan [12]) There exist a distribution function $G \varepsilon \mathbf{D}(\Lambda)$ and a function $r$ which has a $\rho$-varying derivative ( $-1<\rho<\infty$ ) such that $F(x)=G(r(x))$ for $x>0$.
(d) (Haan [12]) There exists a distribution function $G \varepsilon D(\Lambda)$ such that $F(x)=G\left(e^{x}\right)$.

Note that we can take

$$
f_{a}(t)=g_{a}(r(t)) t /(p+1) r(t) \quad \text { in }(c)
$$

and

$$
f_{a}(t)=g_{a}\left(e^{t}\right) e^{-t} \quad \text { in }(\mathrm{d})
$$

where $f_{a}$ and $g_{a}$ are auxiliary functions of $F$ and $G$, respectively.

THEOREM 1.5. (Necessary conditions.) For a distribution function $F$, let

$$
b(s)=\bar{F}^{-1}(1 / s), \quad a(s)=b(e s)-b(s)
$$

If $F \in \mathrm{D}(\Lambda)$, then the following results hold.
(a) (Marcus and Pinsky [13]) The function $a(s)$ is slowly varying at infinity.
(b) (Haan [12]) If $b(\infty)=\infty$, then $b(s)$ is slowly varying at infinity. If $b(\infty)<\infty$, then $b(\infty)-b(s)$ is slowly varying at infinity.

THEOREM 1.6. (Gnedenko [8]) There exist $a>0$ and $b_{n}, n=1,2, \ldots$ such that

$$
F^{n}\left(a x+b_{n}\right) \rightarrow \Lambda(x)
$$

if and only if $F(\log x)$ is $-\alpha$-varying at infinity and $\alpha a=1$.

Resnick [19] proved the following theorem of tail equivalence and asymptotic distributions of extreme statistics.

THEOREM 1.7. Let $F, G$ be distribution functions and let $H$ be an extreme value distribution. Suppose $F \in \mathbf{D}(H)$ and that $F^{n}\left(a_{n} x+b_{n}\right)+H(x)$ for normalizing constants $a_{n}>0, b_{n}, n=1,2, \cdots$. Then, for some $A>0, B: \quad G^{n}\left(a_{n} x+b_{n}\right) \rightarrow H(A x+B)$ if and only if

$$
\begin{aligned}
& x_{F}^{0}=x_{G}^{0}=x^{0}, \\
& \lim _{x \uparrow x^{0}} \frac{1-F(x)}{1-G(x)} \text { exists. }
\end{aligned}
$$

Moreover,
(a) if $H=\Phi_{\alpha}$, then $B=0$ and $\lim _{x \rightarrow \infty}[1-F(x)] /[1-G(x)]=A^{\alpha}$;
(b) if $H=\Psi_{\alpha}$; then $B=0$ and $\lim _{x \uparrow x^{0}}[1-F(x)] /[1-G(x)]=A^{-\alpha}$;
(c) if $H=\Lambda$, then $A=1$ and $\lim _{x+x^{0}}[1-F(x)] /[1-G(x)]=e^{B}$.

### 1.2. The domain of attraction of ${ }_{\alpha}$

We show some properties of normalizing constants of the extreme statistic from a distribution which belongs to $D\left(\Psi_{\alpha}\right)$.

THEOREM 2.1. Let $F$ and $G$ be distribution functions. Suppose $F \in \mathrm{D}\left(\Psi_{\alpha}\right)$ or there exist $a_{n}>0$ and $b_{n}$ such that

$$
\begin{equation*}
F^{n}\left(a_{n} x+b_{n}\right)+\psi_{\alpha}(x) \tag{2.1}
\end{equation*}
$$

and there exist $\alpha_{n}>0$ and $\beta_{n}$ such that

$$
\begin{equation*}
G^{n}\left(\alpha_{n} x+\beta_{n}\right)+H(x), \quad H \text { nondegenerate. } \tag{2.2}
\end{equation*}
$$

Then there exists $c_{0}\left(0<c_{0}<\infty\right)$ such that

$$
\begin{equation*}
\lim _{n \rightarrow \infty} a_{n} / \alpha_{n}=c_{0} \quad \text { and } \quad x_{F}^{0}=x_{G}^{0}\left(=x^{0}, \text { say }\right)<\infty, \tag{2.3}
\end{equation*}
$$

if and only if there exists $c_{1}\left(0<c_{1}<\infty\right)$ such that

$$
\begin{equation*}
\lim _{x \uparrow x_{1} 1-G(x)} \frac{1-F(x)}{}=c_{1}, \tag{2.4}
\end{equation*}
$$

where $x_{1}=x_{F}^{0}$ or $x_{G}^{0}$.
Moreover, if (2.3) or (2.4) holds, then there exist $A>0$ and $B$ such that $H(x)=\Psi_{\alpha}(A x+B)$.

PROOF. For $s>0$, define

$$
\begin{aligned}
& a(s)=\left\{x_{F}^{0}-\bar{F}^{-1}(1 / s)\right\}^{-1} \\
& \alpha(s)=\left\{x_{G}^{0}-\bar{G}^{-1}(1 / s)\right\}^{-1}, \\
& \beta(s)=\bar{G}^{-1}(1 / s)
\end{aligned}
$$

and

$$
\alpha^{\prime}(s)=\beta(e s)-\beta(s) .
$$

Sufficiency. By (2.4) it is easily seen that $x_{1}^{0}=x_{F}^{0}=x_{G}^{0}=x^{0}<\infty$.

From Theorem 1.2 we get that $1-F\left(x^{0}-1 / x\right)$ is $-\alpha$-varying. Then by (2.4) we have that $1-G\left(x^{0}-1 / x\right)$ is also $-\alpha$-varying, too. Hence we have $G$ $\varepsilon \mathrm{D}\left(\Psi_{\alpha}\right)$ and $H(x)=\Psi_{\alpha}(A x+B)$. By Lemma 0.2 in Chapter 0 and Theorem 1.2 we can suppose without loss of generality that $a_{n}=a(n)$ and $\alpha_{n}=A \alpha(n)$. By (2.4) and Theorem 0.1 (c) in Chapter 0 we have

$$
\lim _{n \rightarrow \infty} a_{n} / \alpha_{n}=c_{1}^{-1 / \alpha} / A
$$

Necessity. By (2.2), $x_{G}^{0}<\infty$ and Theorems 1.1, 1.2 and 1.3 it holds that $H(x)=\Lambda(A x+B)$ or $H(x)=\Psi_{B}(A x+B)$, where $A, \beta>0$. If $H(x)=\Lambda(A x+B)$, then we can take $\alpha_{n}=A \alpha^{\prime}(n)$. By Theorem 1.5 (a) $\alpha^{\prime}(s)$ is slowly varying. On the other hand, $a(s)$ is $-\alpha^{-1}$-varying. Therefore, (2.3) does not hold. Thus we have $H(x)=\Psi_{B}(A x+B)$ and we can suppose that $\alpha_{n}=A \alpha(n)$. Since $a(s)$ and $\alpha(s)$ are non-increasing and $a(s)$ is $-\alpha^{-1}$-varying, we have

$$
\lim _{s \rightarrow \infty} a(s) / A \alpha(s)=c_{0}
$$

Hence we have that $\alpha(s)$ is also $-\alpha^{-1}$-varying, too. By Theorem 0.1 (c) in Chapter 0 it holds that

$$
\lim _{x+x^{0} 1-G(x)} \frac{1-F(x)}{}=\left(A c_{0}\right)^{-\alpha}
$$

So we have $B=\alpha$. Q.E.D.

COROLLARY 2.1. Let $F$ be a distribution function with endpoint $x_{F}^{0}=0$ and $0<c<\infty$. Then

$$
\lim _{x \uparrow 0} \frac{1-F(x)}{1-\Psi_{\alpha}(x)}=c
$$

if and only if

$$
F^{n}\left(x / n^{1 / \alpha}\right)+\Psi_{\alpha}\left(c^{1 / \alpha} x\right)
$$

COROLLARY 2.2. Let $F$ be a distribution function with density $f$ and $0<c<\infty$. Then

$$
F^{n}(x / n)+\Psi_{1}(c x)
$$

if and only if

$$
\lim _{x \uparrow 0} f(x)=c \text { and } f(x)=0 \quad \text { for } x>0
$$

REMARK 2.1. Theorem 2.1 is an extension of Theorem 1.7 (b) with a simple proof.

REMARK 2.2. Corollary 2.2 is closely related to the order of efficient estimators dealt with in Section 4.4.

### 1.3. The domain of attraction of $\Lambda$

In this section we consider the distribution functions which belong to $\mathbf{D}(\Lambda)$.

First we prove four theorems useful in choosing normalizing constants.

THEOREM 3.1. Let $F$ be a distribution function.
(a) Suppose $F \in \mathbf{D}(\Lambda)$ or there exist $a_{n}>0$ and $b_{n}$ such that

$$
\begin{equation*}
F^{n}\left(a_{n} x+b_{n}\right)+\Lambda(x) \tag{3.1}
\end{equation*}
$$

Then

$$
\begin{equation*}
\lim _{n \rightarrow \infty} n\left\{1-F\left(b_{n}\right)\right\}=1 \tag{3.2}
\end{equation*}
$$

(b) Conversely, if $F \in \mathrm{D}(\Lambda)$, then (3.1) holds with $b_{n}$ which satisfies (3.2) and $a_{n}=f_{a}\left(b_{n}\right)$, where $f_{a}$ is defined in Theorem 1.3.

PROOF. By Lemma 1.1 and Theorem 1.3 (b), (c), the proof is trivial.

THEOREM 3.2. Let $F$ and $G$ be distribution functions. Suppose there exist $a_{n}>0, b_{n}$ and $\alpha_{n}>0$ such that (3.1) holds, and it holds

$$
\begin{equation*}
G^{n}\left(a_{n} x+b_{n}\right) \rightarrow \Lambda(A x+B), \tag{3.3}
\end{equation*}
$$

where $A>0$. Then we have

$$
\begin{equation*}
\lim _{n \rightarrow \infty} \alpha_{n} / a_{n}=A \tag{3.4}
\end{equation*}
$$

PROOF. For $s>0$, let $b(s)=\bar{F}^{-1}(1 / s)$ and $\beta(s)=\bar{G}^{-1}(1 / s)$. By Lemma 0.2 and Theorem 0.2 in Chapter 0 we can suppose without loss of generality that $a_{n}=b(e n)-b(n), b_{n}=b(n)=\beta\left(e^{B}\right)$ and $a_{n}=$ $\beta\left(e^{A} e^{B} n\right)-\beta\left(e^{B} n\right)$. It holds that

$$
\beta\left(e^{B}[e n]\right) \leq \beta\left(e e^{B} n\right) \leq \beta\left(e^{B}([e n]+1)\right) \text { for all } n \text {, }
$$

where [en] is the greatest integer less than or equal to en. Thus we have

$$
\begin{equation*}
\frac{b([e n])-b(n)}{b(e n)-b(n)} \leq \frac{\beta\left(e e^{B} n\right)-B\left(e^{B} n\right)}{b(e n)-b(n)} \leq \frac{b([e n]+1)-b(n)}{b(e n)-b(n)} . \tag{3.5}
\end{equation*}
$$

As $b$ is non-decreasing, we have for fixed $c(1<c<e)$ and sufficiently large $n$

$$
1 \geq \frac{b([e n])-b(n)}{b(e n)-b(n)} \geq \frac{b(e n)-b(n)}{b(e n)-b(n)} .
$$

By Theorem 1.3 (d) we have

$$
\lim _{n \rightarrow \infty} \frac{b(c n)-b(n)}{b(e n)-b(n)}=\log c .
$$

Hence we have

$$
\begin{equation*}
\lim _{n \rightarrow \infty} \frac{b([e n])-b(n)}{b(e n)-b(n)}=1 . \tag{3.6}
\end{equation*}
$$

Similarly

$$
\begin{equation*}
\lim _{n \rightarrow \infty} \frac{b([e n]+1)-b(n)}{b(e n)-b(n)}=1 \tag{3.7}
\end{equation*}
$$

By (3.5), (3.6) and (3.7), it holds that

$$
\begin{equation*}
\lim _{n+\infty} \frac{B\left(e e^{B} n\right)-B\left(e^{B} n\right)}{b(e n)-b(n)}=1 . \tag{3.8}
\end{equation*}
$$

On the other hand, by Theorem 1.3 (d) it holds that

$$
\begin{equation*}
\lim _{n \rightarrow \infty} \frac{B\left(e^{A} e^{B} n\right)-B\left(e^{B} n\right)}{B\left(e e^{B} n\right)-B\left(e^{B} n\right)}=A . \tag{3.9}
\end{equation*}
$$

By (3.8) and (3.9) we have (3.4). Q.E.D.

The converse of Theorem 3.2 becomes the following theorem.

THEOREM 3.3. Let $F$ and $G$ be distribution functions. Suppose there exist $a_{n}>0, b_{n}, \alpha_{n}>0$ and $\beta_{n}$ such that (3.1) holds, and it holds that

$$
\begin{equation*}
G^{n}\left(\alpha_{n} x+\beta_{n}\right)+\Lambda(x) . \tag{3.10}
\end{equation*}
$$

(a) If $x_{F}^{0}=x_{G}^{0}=\infty$ and for $0 \leq c \leq \infty$,

$$
\begin{equation*}
\lim _{n \rightarrow \infty} a_{n} / \alpha_{n}=c, \tag{3.11}
\end{equation*}
$$

then

$$
\lim _{n \rightarrow \infty} b_{n} / \beta_{n}=c .
$$

(b) If $x_{F}^{0}=x_{G}^{0}=x^{0}<\infty$ and for $0 \leq c \leq \infty$, (3.11) holds, then

$$
\lim _{n \rightarrow \infty} \frac{x^{0}-b_{n}}{x^{0}-\beta_{n}}=c .
$$

PROOF. For $s>0$, define

$$
a(s)=b(e s)-b(s)
$$

and

$$
\alpha(s)=\beta(e s)-\beta(s)
$$

where $b(s)=\bar{F}^{-1}(1 / s)$ and $B(s)=\bar{G}^{-1}(1 / s)$. By Lemma 0.2 in Chapter 0 we can suppose without loss of generality that $a_{n}=a(n), b_{n}=b(n), \alpha_{n}=\alpha(n)$ and $B_{n}=\beta(n)$.
(a) By Theorem 1.5 (b) we have

$$
b(s) \sim \int_{1}^{s} \frac{a(t)}{t} d t
$$

and

$$
B(s) \sim \int_{-1}^{s} \frac{\alpha(t)}{t} d t
$$

Suppose (3.11) holds, then by Theorem 1.5 (a) it holds that

$$
\lim _{s \rightarrow \infty} a(s) / \alpha(s)=c .
$$

Thus we have

$$
\begin{gathered}
\lim _{s \rightarrow \infty} \frac{b(s)}{\beta(s)}=\lim _{s+\infty} \frac{\int_{1}^{s} \frac{a(t)}{t} d t}{\int_{i}^{s} \frac{\alpha(t)}{t} d t}=c . \\
-17-
\end{gathered}
$$

(b) By Theorem 1.5 (b) we have

$$
x^{0}-b(s) \sim \int_{1}^{s} \frac{a(t)}{t} d t
$$

and

$$
x^{0}-\beta(s) \sim \int_{1}^{s} \frac{\alpha(t)}{t} d t,
$$

so that a similar argument as in (a) proves (b). Q.E.D.

COROLLARY 3.1. Let $F$ be a distribution function with infinite endpoint. Then $1-F(\log x)$ is -a-varying if and only if there exists $b_{n}$ such that

$$
F^{n}\left(x / \alpha+b_{n}\right) \rightarrow \Lambda(x)
$$

and $b_{n} \sim \log n / \alpha$, where $\alpha>0$.

PROOF. It is clear from Theorems 1.6 and 3.3.

THEOREM 3.4. Let $F$ and $G$ be distribution functions. Suppose $F \in D(\Lambda)$ or there exist $a_{n}$ and $b_{n}$ such that (3.1) holds. Then there exists $a_{n}>0$ such that

$$
\begin{equation*}
G^{n}\left(a_{n} x+b_{n}\right) \rightarrow \Lambda(A x+B) \quad \text { and } \quad A>0 \tag{3.12}
\end{equation*}
$$

if and only if $x_{F}^{0}=x_{G}^{0}\left(=x^{0}\right.$, say $), \alpha_{n} / a_{n}+A$, and

$$
\begin{equation*}
\lim _{x \uparrow x^{0}} \frac{1-G(x)}{1-F(x)}=e^{-B} . \tag{3.13}
\end{equation*}
$$

PROOF. Sufficiency. By Lemma 1.1 we have

$$
\begin{equation*}
\lim _{n \rightarrow \infty} n\left\{1-F\left(a_{n} x+b_{n}\right)\right\}=e^{-x} \tag{3.14}
\end{equation*}
$$

So it holds that $a_{n} x+b_{n} \rightarrow x^{0}$ as $n \rightarrow \infty$. Hence we have

$$
\lim _{n \rightarrow \infty} \frac{1-G\left(a_{n} x+b_{n}\right)}{1-F\left(a_{n} x+b_{n}\right)}=e^{-B}
$$

Therefore it holds that

$$
\begin{equation*}
\lim _{n \rightarrow \infty} n\left\{1-G\left(a_{n} x+b_{n}\right)\right\}=e^{-(x+B)} \tag{3.15}
\end{equation*}
$$

By $\lim _{n \rightarrow \infty} \alpha_{n} / a_{n}=A>0$, we have (3.12).
Necessity. By Theorem 3.2 we have $\lim \alpha_{n} / a_{n}=A . \operatorname{By}$ (3.1), (3.12) and Lemma 1.1 we have (3.14) and (3.15), hence we get $b_{n} \rightarrow x_{F}^{0}$ and $b_{n} \rightarrow x_{G}^{0}$. So it holds that $x_{F}^{0}=x_{G}^{0}=x^{0}$. By Lemma 0.2 in Chapter 0 we can suppose without loss of generarity that $b_{n}$ is defined by $\bar{F}^{-1}(1 / n)$, and hence $b_{n} \uparrow x^{0}$ as $n \rightarrow \infty$. For any $x$ sufficiently near $x^{0}\left(x<x^{0}\right)$, there exists an $n$ such that $b_{n} \leq x \leq b_{n+1}$. Then we have

$$
\frac{1-G\left(b_{n+1}\right)}{1-F\left(b_{n}\right)} \leq \frac{1-G(x)}{1-F(x)} \leq \frac{1-G\left(b_{n}\right)}{1-F\left(b_{n+1}\right)}
$$

By (3.14) and (3.15), taking the limits of above inequalities, we have (3.13). Q.E.D.

REMARK 3.1. Theorem 3.4 is an extension of Theorem 1.7 (c) with a simpler proof.

REMARK 3.2. Given a distribution function $G \in D(\Lambda)$, from Theorems 3.1 and 3.2 we can present the following procedure to find normalizing constants of $G$. We first choose an appropriate simple distribution function $F$ such that (3.13) holds for some $B$, seek $b_{n}$ which satisfy (3.2) and then define $a_{n}=f_{a}\left(b_{n}\right)$. The explicit form of the function $f_{a}$ is given by Theorem 1.3 (c).

The following two theorems determine the transformations of the normilizing constants induced by a transformations of the underlying random variable.

THEOREM 3.5. Let $a_{n}$ and $b_{n}$ be normalizing constants of a distribution function $F \in D(\Lambda)$ with infinite endpoint. For $x>0$, let $G(x)=F(r(x))$.
where $r$ is a function which has a $\rho$-varying derivative $(-1<\rho<\infty)$. Then $G \in \mathrm{D}(\Lambda)$, and

$$
G^{n}\left(\alpha_{n} x+\beta_{n}\right)+\Lambda(x)
$$

where $a_{n}=a_{n} r^{-1}\left(b_{n}\right) /(\rho+1) b_{n}$ and ${ }^{\beta}{ }_{n}=r^{-1}\left(b_{n}\right)$.

PROOF. By Theorem 1.4 (c) it holds that $G \varepsilon \mathrm{D}(\Lambda)$ and $g_{a}(t)=$ $f_{a}(r(t)) t /(\rho+1) r(t)$, where $f_{a}$ and $g_{a}$ are auxiliary functions of $F$ and $G$, respectively. Then we can suppose without loss of generality that $\beta_{n}=$ $\bar{G}^{-1}(1 / n)$ and $\alpha_{n}=g_{a}\left(\beta_{n}\right)$ (see Theorem $1.3(b)$ ). The inverse function $r^{-1}$ of $r$ is well determined, because $r$ is continuous and strictly increasing. Thus we have $B_{n}=r^{-1}\left(b_{n}\right)$ and $\alpha_{n}=a_{n} r^{-1}\left(b_{n}\right) /(\rho+1) b_{n}$. Q.E.D.

COROLLARY 3.2. Let $F$ be a distribution function with infinite endpoint. For $\alpha>0$ and $\rho>0$, we have

$$
\frac{1-F\left(t+x t^{1-\alpha} / \alpha \rho\right)}{1-F(t)}+e^{-x} \quad \text { as } t+\infty
$$

if and only if $1-F\left((\log x)^{1 / \alpha}\right)$ is. $-\rho$-varying.

PROOF. It is clear from Theorems 1.6 and 3.5.

THEOREM 3.6. Let $\alpha_{n}$ and $\beta_{n}$ be normalizing constants of a distribution function $G \in \mathbf{D}(\Lambda)$ with infinite endpoint. Let $F(x)=G\left(e^{x}\right)$. Then $F \in \mathbf{D}(\Lambda)$ and

$$
F^{n}\left(a_{n} x+b_{n}\right)+\Lambda(x),
$$

where $a_{n}=\alpha_{n} / \beta_{n}$ and $b_{n}=\log \beta_{n}$.
PROOF. By Theorem $1.4(\mathrm{~d})$ it holds that $F \in \mathrm{D}(\Lambda)$ and $f_{a}(t)=g_{a}\left(e^{t}\right) e^{-t}$, where $f_{a}$ and $g_{a}$ are auxiliary functions of $F$ and $G$, respectively. We can suppose without loss of generality that $\beta_{n}=\bar{G}^{-1}(1 / n)$ and $\alpha_{n}=g_{a}{ }^{\left(\beta_{n}\right) \text { (see }}$

Theorem $1.3(b))$. Then we have $b_{n}=\bar{F}^{-1}(1 / n)=\log \beta_{n}$ and $a_{n}=f_{a}\left(b_{n}\right)$ $=g_{a}\left(B_{n}\right) \exp \left(-b_{n}\right)=\alpha_{n} / \beta_{n} . \quad$ Q.E.D.

Now we show some simple sufficient conditions that a distribution function belongs to $\mathrm{D}(\Lambda)$ and determine the normalizing constants.

THEOREM 3.7. Let $F$ be a distribution function. Suppose that there exist $\alpha>0, a>0, c>0$ and $b \varepsilon \mathrm{R}$ such that

$$
\lim _{x \rightarrow \infty} \frac{1-F(x)}{a x^{b} e^{-c x^{\alpha}}}=1
$$

For $\mu \varepsilon \mathbf{R}$ and $\sigma>0$, let $F_{*}(x)=F((x-\mu) / \sigma)$. Then $F_{*} \varepsilon D(\Lambda)$ and

$$
F_{*}^{n}\left(a_{n}^{*} x+b_{n}^{*}\right) \rightarrow \Lambda(x),
$$

where $a_{n}^{*}=\sigma a_{n}, b_{n}^{*}=\sigma b_{n}+\mu, a_{n}=((\log n) / c)^{1 / \alpha-1} / \alpha c$ and $b_{n}=((\log n) / c)^{1 / a}$ $+\{(b / a)(\log (\log n)-\log c)+\log a\} /\left\{((\log n) / c)^{1-1 / \alpha} \alpha c\right\}$.

PROOF. Consider the following distribution functions

$$
G_{0}(x)=1-e^{-x}, \quad x>0
$$

and

$$
G(x)=1-a x^{b} e^{-c x^{\alpha}}, \quad x>x_{1},
$$

where $x_{1}$ is a constant such that $G(x), G^{\prime}(x)>0$ for all $x>x_{1}$. Then $G_{0}$ $\varepsilon \mathbf{D}(\Lambda)$. By Theorem 3.5 and Theorem 1.4 (b) we have $G \varepsilon \mathrm{D}(\Lambda)$. It is easy to show that

$$
n\left\{1-G\left(b_{n}\right)\right\} \rightarrow 1 \quad \text { as } n \rightarrow \infty
$$

By Corollary 3.2 , Lemma 0.2 in Chapter 0 and $a_{n} \sim b_{n}^{1-\alpha / \alpha c}$, we have

$$
G^{n}\left(a_{n} x+b_{n}\right) \rightarrow \Lambda(x)
$$

Thus, by Theorem 1.7 (c), we have

$$
F^{n}\left(a_{n} x+b_{n}\right)+\Lambda(x)
$$

Some obvious calculation gives the statement of the theorem. Q.E.D.

THEOREM 3.8. Suppose a distribution function $F$ has a density $f$ such that

$$
\lim _{x \rightarrow \infty} \frac{f(x)}{\alpha a c x^{\alpha+b-1} e^{-c x^{\alpha}}}=1
$$

where $\alpha>0, a>0, c>0$ and $b \varepsilon \mathbf{R}$. For $\mu \varepsilon \mathbf{R}$ and $\sigma>0$, let $F_{*}(x)=$ $F((x-\mu) / \sigma)$. Then the same conclusion as that of Theorem 3.7 holds.

PROOF. Consider the same distribution function $G$ as in the proof of Theorem 3.7. Let $g(x)=G^{\prime}(x)$, then by the assumption it holds that $\lim _{x \rightarrow \infty} f(x) / g(x)=1$. Thus, by Lemma 0.1 in Chapter 0 , we have

$$
\lim _{x \rightarrow \infty} \frac{1-F(x)}{a x^{b} e^{-c x^{\alpha}}}=\lim _{x \rightarrow \infty} \frac{\int_{x}^{\infty} f(s) d s}{\int_{x}^{\infty} g(s) d s}=1 .
$$

By Theorem 3.7 we have the conclusion. Q.E.D.

THEOREM 3.9. Let $G$ and $G_{*}$ be distribution functions such that $G(x)=$ $F(\log x)$ and $G_{*}(x)=F_{*}(\log x)$ for $x>0$, where $F$ and $F_{*}$ are distribution functions satisfying the conditions in Theorem 3.7. If $\alpha>1$, then $G_{*} \in \mathrm{D}(\Lambda)$ and

$$
G_{*}^{n}\left(\alpha_{n}^{*} x+\beta_{n}^{*}\right) \rightarrow \Lambda(x),
$$

where $\alpha_{n}^{*}=a_{n}^{*} \beta_{n}^{*}, \beta_{n}^{*}=\exp \left(b_{n}^{*}\right)$ and $a_{n}^{*}, b_{n}^{*}$ are the same normalizing constants as that of Theorem 3.7.

PROOF. Let $H(x)=1-\exp \left\{-c(\log x)^{\alpha}\right\}$, for $x>1$. By Theorem 1.4 (a) we have $H \in D(\Lambda)$. Thus by Theorem 1.4 (b) we have $G \varepsilon D(\Lambda)$. By the relation $G_{*}(x)=G\left(e^{-\mu / \sigma_{x}} x^{1 / \sigma}\right)$ and Theorem 1.4 (c) we have $G_{*} \varepsilon D(\Lambda)$.

Therefore, by Theorems 3.6 and 3.7 we have the conclusion. Q.E.D.

The following theorem can be proved similarly as Theorem 3.8.

THEOREM 3.10. Let $G$ and $G_{*}$ be distribution functions. Suppose $G(x)=$ $F(\log x)$ and $G_{*}(x)=F_{*}(\log x)$ for $x>0$, where $F$ and $F_{*}$ are distribution functions satisfying the conditions in Theorem 3.8. If $\alpha>1$, then $G_{*} \varepsilon \mathrm{D}(\Lambda)$ and the same conclusion as that of Theorem 3.9 holds.

REMARK 3.3. (a) Theorems $3.7-3.10$ are very simple and the conditions are convenient to verify. In the next section we will see that many distribution functions which are used in applied statistics satisfy these conditions.
(b) Note that $\alpha>0$ in Theorems 3.7 and 3.8, whereas $\alpha>1$ in Theorems 3.9 and 3.10.
(c) It is well-known that $b_{n}$ is given by $\bar{F}^{-1}(1 / n)$ (see Theorem 1.3 (b)). But with some distributions its exact values can not be expressed by sample size $n$ in simple forms as in Theorems 3.7-3.10.

### 1.4. Examples

We shall apply the results of Section 1.3 to some specific distribution functions which are often used in applied statistics.

EXAMPLE 4.1 (Inverse Gaussian distribution). Suppose a distribution function $F$ has a density function

$$
f(x)=\left\{\begin{array}{cc}
\left(\frac{\lambda}{2 \pi x^{3}}\right)^{1 / 2} \exp -\left\{\frac{\lambda(x-\mu)^{2}}{2 \mu^{2} x}\right\}, & x>0 \\
0, & \text { otherwise }
\end{array}\right.
$$

where $\mu>0$ and $\lambda>0$. Then by Theorem 3.8 we have $F \in D(\Lambda)$ and

$$
F^{n}\left(a_{n} x+b_{n}\right)+\Lambda(x)
$$

where $a_{n}=2 \mu^{2} / \lambda$ and $b_{n}=\mu^{2}\left\{2 \log n-3 \log (\log n)+\log \left(\lambda^{2} /\left(4 \pi \mu^{2}\right)\right)+2 \lambda / \mu\right\} / \lambda$.

EXAMPLE 4.2 (Gamma distribution and Mixture of gamma distributions).
(I) Suppose a distribution function $G$ has a density function

$$
g(x)=x^{p-1} e^{-x} / \Gamma(p),
$$

where $p>0$ and $\Gamma(\cdot)$ is the gamma function. For $\mu \varepsilon R$ and $\sigma>0$, let $G_{*}(x)=G((x-\mu) / \sigma)$. Then by Theorem 3.8 we have $G_{*} \in \mathrm{D}(\Lambda)$ and

$$
G_{*}^{n}\left(a_{n}^{*} x+b_{n}^{*}\right)+\Lambda(x)
$$

where $a_{n}^{*}=\sigma a_{n}=\sigma, b_{n}^{*}=\sigma b_{n}+\mu, a_{n}=1$ and $b_{n}=\log [n / \Gamma(p)]+(p-1) \log (\log n)$.

Note that Gumbel's approximation

$$
u_{2}=\log [n / \Gamma(p)]+(p-1) \log \log [n / \Gamma(p)]
$$

of $\inf \{x: 1-G(x) \leq 1 / n\}$ (see Gumbel [11], p.145) is not an exact normalizing constant.
(II)

$$
F(x)=p G\left(\left(x-\mu_{1}\right) / \sigma_{1}\right)+q G\left(\left(x-\mu_{2}\right) / \sigma_{2}\right),
$$

where $\mu_{1}, \mu_{2} \varepsilon R, \sigma_{1}, \sigma_{2}>0, p, q>0$ and $p+q=1$. The density function of $F$ is

$$
f(x)=p g\left(\left(x-\mu_{1}\right) / \sigma_{1}\right) / \sigma_{1}+q g\left(\left(x-\mu_{2}\right) / \sigma_{2}\right) / \sigma_{2}
$$

(1) If $\sigma_{1}=\sigma_{2}=\sigma$, then

$$
f(x) /\{g(x / \sigma) / \sigma\} \rightarrow p e^{\mu_{1} / \sigma}+q e^{\mu_{2} / \sigma} \quad \text { as } x+\infty
$$

Hence, by Theorem 3.8 we have $F \in \mathbf{D}(\Lambda)$ and

$$
F^{n}\left(a_{n}^{1} x+b_{n}^{1}\right)+\Lambda(x)
$$

where $a_{n}^{1}=\sigma$ and $b_{n}^{1}=\sigma\left(b_{n}+\log \left(p e^{\mu_{1} / \sigma}+q e^{\mu_{2} / \sigma}\right)\right)$.
(2) If $\sigma_{1}<\sigma_{2}$, then

$$
f(x) /\left\{q g\left(\left(x-\mu_{2}\right) / \sigma_{2}\right) / \sigma_{2}\right\}+1 \quad \text { as } x \rightarrow \infty
$$

Hence, by Theorem 3.8 we have $F \in D(\Lambda)$ and

$$
F^{n}\left(a_{n}^{2} x+b_{n}^{2}\right) \rightarrow \Lambda(x)
$$

where $a_{n}^{2}=\sigma_{2}$ and $b_{n}^{2}=\sigma_{2}\left(b_{n}+\log q\right)+\mu_{2}$.

EXAMPLE 4.3 (Normal distribution, Lognormal distribution and Mixture of normal distributions).
(I) Suppose $G$ is a distribution function such that

$$
G(x)=\Phi(\log x) \quad \text { for } x>0
$$

where $\Phi$ is a standard normal distribution function. For $\mu \varepsilon \mathbf{R}$ and $\sigma>0$ let $\Phi_{*}(x)=\Phi((x-\mu) / \sigma)$ and $G_{*}(x)=\Phi_{*}(\log x)$ for $x>0$. Then by Theorem 3.8 we have $\Phi_{*} \varepsilon \mathbf{D}(\Lambda)$ and

$$
\Phi_{*}^{n}\left(a_{n}^{*} x+b_{n}^{*}\right) \rightarrow \Lambda(x)
$$

where $a_{n}^{*}=\sigma a_{n}, b_{n}^{*}=\sigma b_{n}+\mu, a_{n}=(2 \log n)^{-1 / 2}$ and $b_{n}=(2 \log n)^{1 / 2}-(\log (\log n)+\log 4 \pi) / 2(2 \log n)^{1 / 2}$.

On the other hand, by Theorem 3.9 we have $G_{*} \varepsilon D(\Lambda)$ and

$$
G_{\star}^{n}\left(\alpha_{n}^{+} x+\beta_{n}^{*}\right)+\Lambda(x)
$$

where $\alpha_{n}^{*}=a_{n}^{*} \beta_{n}^{*}$ and $\beta_{n}^{*}=\exp \left(b_{n}^{*}\right)$.
Approaches presented in Galambos [7] (p.65 and p.67) and Singpurwalla
[21] to evaluate normalizing constants seem to be more complicated than ours. It is hard to evaluate $\bar{\Phi}^{-1}(1 / n)$ and sometimes inadequate sequences $(2 \log n)^{1 / 2}$ are claimed to be $b_{n}$ (for example see David [2], p.209).

Suppose $F$ is a distribution function such that

$$
\begin{equation*}
F(x)=p \Phi\left(\left(x-\mu_{1}\right) / \sigma_{1}\right)+q \Phi\left(\left(x-\mu_{2}\right) / \sigma_{2}\right), \tag{II}
\end{equation*}
$$

where $\mu_{1}, \mu_{2} \varepsilon R, \sigma_{1}, \sigma_{2}>0, p, q>0$ and $p+q=1$. The density of $F$ is

$$
f(x)=p \phi\left(\left(x-\mu_{1}\right) / \sigma_{1}\right) / \sigma_{1}+q \phi\left(\left(x-\mu_{2}\right) / \sigma_{2}\right) / \sigma_{2},
$$

where $\phi(x)=(2 \pi)^{-1 / 2} \exp \left(-x^{2} / 2\right)$.
(1) If $\sigma_{1}=\sigma_{2}=\sigma$ and $\mu_{1}<\mu_{2}$, then

$$
f(x) /\left\{q \phi\left(\left(x-\mu_{2}\right) / \sigma\right) / \sigma\right\} \rightarrow 1 \quad \text { as } x+\infty .
$$

Hence by Theorem 3.8 we have $F \in \mathrm{D}(\Lambda)$ and

$$
F^{n}\left(a_{n}^{1} x+b_{n}^{1}\right)+\Lambda(x),
$$

where $a_{n}^{1}=\sigma a_{n}$ and $b_{n}^{1}=\sigma\left(b_{n}+a_{n} \log q\right)+\mu_{2}$.
(2) If $\sigma_{1}<\sigma_{2}$, then

$$
f(x) /\left\{q \phi\left(\left(x-\mu_{2}\right) / \sigma_{2}\right) / \sigma_{2}\right\}+1 \quad \text { as } x+\infty .
$$

Hence by Theorem 3.8 we have $F \in \mathbf{D}(\Lambda)$ and

$$
F^{n}\left(a_{n}^{2} x+b_{n}^{2}\right)+\Lambda(x),
$$

where $a_{n}^{2}=\sigma_{2} a_{n}$ and $b_{n}^{2}=\sigma_{2}\left(b_{n}+a_{n} \log q\right)+\mu_{2}$.

## CHAPTER 2

## ASYMPTOTIC THEORY OF EXTREME STATISTIC - MULTIVARIATE CASE

### 2.1. Introduction

In this chapter, we establish some properties of multivariate extreme value distributions, and by using the results of Marshall and Olkin [14] (see Propositions $1.1-1.3$ ) we extend some of the results given by Resnick [19] (see Theorem 1.7 in Section 1.1) to the multivariate case. We may use the same notations as in Marshall and Olkin [14].

For $\mathbf{a}, \mathbf{b}, \mathbf{x} \in \mathbf{R}^{k}$, write $\mathbf{a x}+\mathbf{b}$ to denote the vector

$$
\left(a_{1} x_{1}+b_{1}, \cdots, a_{k} x_{k}+b_{k}\right)
$$

Basic arithmetical operations are always meant componentwise. Let $\mathbf{x}^{(1)}, \mathbf{x}^{(2)}$, ... be a sequence of independent $k$-dimensional random vectors with common distribution function $F$ and let
$Z_{i}^{(n)}=\max _{i} X_{i}^{(j)}, \quad i=1, \cdots, k$.
If there exist $\mathbf{a}^{(n)}>0, \mathbf{b}^{(n)} \varepsilon \mathbf{R}^{k}, n=1,2, \cdots\left(\mathbf{a}^{(n)}>0\right.$ means $a_{i}^{(n)}>0$, $i=1, \cdots, k)$ such that $\left(\mathbf{Z}^{(n)}-\mathbf{b}^{(n)}\right) / \mathbf{a}^{(n)}$ converges in distribution to a random vector $\mathbf{U}$ with nondegenerate distribution function $H$ (i.e., all univariate marginals of $H$ are nondegenerate), then $F$ is said to be in the domain of attraction of $H$ with the notation $F \varepsilon \mathbf{D}(H)$ and $H$ is said to be a multivariate extreme value distribution. The convergence in distribution is equivalent to the condition

$$
\begin{equation*}
\lim _{n \rightarrow \infty} F^{n}\left(\mathbf{a}^{(n)} \mathbf{x}+\mathbf{b}^{(n)}\right)=H(\mathbf{x}) \quad \text { for all } \mathbf{x} \tag{1.1}
\end{equation*}
$$

because multivariate extreme value distributions are continuous (see Theorem 1.1).

Note that if $\left(\mathbf{Z}^{(n)}-\mathbf{b}^{(n)}\right) / \mathbf{a}^{(n)}$.converges in distribution to $\mathbf{U}$, then
the $i$ th component of $\left(\mathbf{z}^{(n)}-\mathbf{b}^{(n)}\right) / \mathbf{a}^{(n)}$ converges to the $i$ th component of $\mathbf{U}$ and thus normalizing constants $\left\{a_{i}^{(n)}\right\},\left\{b_{i}^{(n)}\right\}$ can be determined from wellknown univariate considerations, $i=1, \cdots, k$.

For $k>1$, let $G$ be the joint distribution of ( $Y_{1}, Y_{2}, \cdots, Y_{k}$ ) then $G_{i_{1} i_{2}} \cdots i_{m}$ denotes the joint distribution of ( $y_{i_{1}}, Y_{i_{2}}, \cdots, Y_{i_{m}}$ ), and $\bar{G}_{i_{1} i_{2}} \cdots i_{m}$ denotes the survival function of ( $y_{i_{1}}, Y_{i_{2}}, \cdots, y_{i_{m}}$ ), i.e.,

$$
\bar{G}_{i_{1} i_{2}} \cdots i_{m}\left(y_{i_{1}}, \cdots, y_{i_{m}}\right)=P\left(y_{i_{1}}>y_{i_{1}}, \cdots, y_{i_{m}}>y_{i_{m}}\right)
$$

where $1 \leq i_{1}<i_{2}<\cdots<i_{m} \leq k$. Let

$$
\mathbf{x}_{G}^{0}=\left(x_{G_{1}}^{0}, \cdots, x_{G_{k}}^{0}\right)
$$

where $x_{G_{i}}^{0}$ is the endpoint of $G_{i}, i=1,2, \cdots, k$.
Now we summarize some multivariate results which are used in later sections.

We make extensive use of the following result (see Marshall and Olkin [14] and Theorem 5.3.1 of Galambos [7]).

LEMMA 1.1. Equation (1.1) is equivalent to

$$
\lim _{n \rightarrow \infty} n\left\{1-F\left(\mathbf{a}^{(n)} \mathbf{x}+\mathbf{b}^{(n)}\right)\right\}=-\log H(\mathbf{x})
$$

for all $\mathbf{x}$ such that $0<H(\mathbf{x})<1$.

It is well-known that the weak convergence of distributions implies the weak convergence of any finite-dimensional marginal distribution (for example see Billingsley [1], p.30). Thus Lemma 1.1 holds for any marginal distribution of $F$.

Following results are seen in Galambos [7] (Chapter 5).

THEOREM 1.1. Let $H$ be an extreme value distribution. Then $H$ is continuous, and its univariate marginals $H_{i}(i=1,2, \cdots, k)$ belongs to one of the types $\Phi_{\alpha}, \Psi_{\alpha}$ and $\Lambda$.

THEOREM 1.2. Equation (1.1) holds $i_{j}$ and only if for each fixed $\left\{i_{1}, i_{2}, \cdots, i_{m}\right\}$ and for all $\mathbf{x}$ such that $H(\mathbf{x})>0$,

$$
\begin{align*}
\lim _{n \rightarrow \infty} & n \bar{F}_{i_{1} i_{2}} \cdots i_{m}\left(a_{i_{1}}^{(n)} x_{i_{1}}+b_{i_{1}}^{(n)}, \cdots, a_{i_{m}}^{(n)} x_{i_{m}}+b_{i_{m}}^{(n)}\right)  \tag{1.2}\\
& =h_{i_{1} i_{2} \cdots i_{m}}\left(x_{i_{1}}, \cdots, x_{i_{m}}\right)
\end{align*}
$$

are finite and the function

$$
\begin{equation*}
\left.H(\mathbf{x})=\underset{m=1}{\operatorname{expt}} \sum_{\sum_{m}^{m}}^{(-1)^{m}} \quad \Sigma i_{1}<\cdots<i_{m} \leq k i_{1} i_{2} \cdots i_{m}\left(x_{i_{1}}, \cdots, x_{i_{m}}\right)\right\} \tag{1.3}
\end{equation*}
$$

is a nondegenerate distribution function. The actual limit distribution function of $F^{n}\left(\mathbf{a}^{(n)} \mathbf{x}+\mathbf{b}^{(n)}\right)$ is the one given in (1.3).

COROLLARY 1.1. Assume that $\left(\mathbf{z}^{(n)}-\mathbf{b}^{(n)}\right) / \mathbf{a}^{(n)}$ has a nondegenerate asymptotic distribution $H(\mathbf{x})$. Then the components of $\left(\mathbf{z}^{(n)}-\mathbf{b}^{(n)}\right) / \mathbf{a}^{(n)}$ are asymptotically independent if and only if the limits in (1.2) are identically zero for $m=2$.

The following results were proved by Marshall and Olkin [14].

PROPOSITION 1.1. Let $H$ be an extreme value distribution such that $H_{i}=\Phi_{\alpha_{i}}, \alpha_{i}>0, i=1, \cdots, k$. Then $F \in \mathrm{D}(H)$ if and only if

$$
\lim _{t \rightarrow \infty} \frac{1-F\left(t x_{1}, \phi_{2}(t) x_{2}, \cdots, \phi_{k}(t) x_{k}\right)}{1-F_{1}(t)}=-\log H(\mathbf{x})
$$

for all $\mathbf{x}$ such that $H(\mathbf{x})>0$, where $\phi_{i}(t)=\bar{F}_{i}^{-1} \bar{F}_{1}(t), i=2, \cdots, k$.
PROPOSITION 1.2. Let $H$ be an extreme value distribution such that $H_{i}=\psi_{\alpha_{i}}, \alpha_{i}>0, i=1, \cdots, k$. Then $F \in \mathrm{D}(H)$ if and only if $\mathbf{x}_{F}^{0} \in \mathbf{R}^{k}$ and

$$
\begin{gathered}
\lim _{t+0} \frac{1-F\left(\left(t x_{1}, \phi_{2}(t) x_{2}, \cdots, \phi_{k}(t) x_{k}\right)+x^{0}\right)}{1-F_{1}\left(x_{F_{1}^{0}}^{0}-t\right)}=-\log H(\mathbf{x}) \\
-30-
\end{gathered}
$$

for all $\mathbf{x}$ such that $H(\mathbf{x})>0$, where $\phi_{i}(t)=x_{F_{i}}^{0}-\bar{F}_{i}^{-1}\left(\bar{F}_{1}\left(x_{F_{1}}^{0}-t\right)\right), i=2, \cdots, k$.

PROPOSITION 1.3. Let $H$ be an extreme value distribution such that $H_{i}=\Lambda, i=1, \cdots, k$. Then $F \varepsilon \mathrm{D}(H)$ if and only if

$$
\lim _{t+x_{F_{1}}^{0}} \frac{1-F(\mathbf{a}(t) \mathbf{x}+\mathbf{b}(t))}{1-F_{1}(t)}=-\log H(\mathbf{x})
$$

for all $\mathbf{x}$ such that $H(\mathbf{x})>0$, where $a_{i}(t)=\bar{F}_{i}^{-1}\left(\bar{F}_{1}(t) / e\right)-\bar{F}_{i}^{-1} \bar{F}_{1}(t), b_{i}(t)=$ $\bar{F}_{i}^{-1} \bar{F}_{1}(t), i=1, \cdots, k$.

### 2.2. Multivariate extreme value distributions

In this section we establish some properties of multivariate extreme value distributions.

THEOREM 2.1. A nondegenerate $k$-dimensional distribution function $H$ is an extreme value distribution if and only if for all $s>0$ there exist vectors $\mathbf{A}^{(s)}>0$ and $\mathbf{B}^{(s)}$ such that

$$
\begin{equation*}
H^{s}\left(\mathbf{A}^{(s)} \mathbf{x}+\mathbf{B}^{(s)}\right)=H(\mathbf{x}) \quad \text { for } a l l \mathbf{x} \in \mathbf{R}^{k} \tag{2.1}
\end{equation*}
$$

PROOF. Sufficiency is obvious so that we shall prove necessity. If $H$ is an extreme value distribution, then there exist a distribution function $F$ and vectors $\mathbf{a}^{(n)}$ and $\mathbf{b}^{(n)}$ such that

$$
\begin{equation*}
\lim _{n \rightarrow \infty} F^{n}\left(\mathbf{a}^{(n)} \mathbf{x}+\mathbf{b}^{(n)}\right)=H(\mathbf{x}) \tag{2.2}
\end{equation*}
$$

It follows from Lemma 1.1 that

$$
\lim _{n \rightarrow \infty} n\left\{1-F\left(\mathbf{a}^{(n)} \mathbf{x}+\mathbf{b}^{(n)}\right)\right\}=-\log H(\mathbf{x})
$$

Hence for all s > 0

where [ns] is the greatest integer less than or equal to $n s$. Then by Lemma 1.1

$$
\begin{equation*}
\lim _{n \rightarrow \infty} F^{n}\left(\mathbf{a}^{([n s])} \mathbf{x}+\mathbf{b}^{([n s])}\right)=H^{1 / s}(\mathbf{x}) \tag{2.3}
\end{equation*}
$$

Hence by (2.2), (2.3) and Lemma 0.2 in Chapter 0 (which can easily be extended to the multivariate case, see also the proof of Theorem 5.2.1 of Galambos [7]), there exist vectors $A^{(s)}>0$ and $B^{(s)}$ such that

$$
H^{s}\left(\mathbf{A}^{(s)} \mathbf{x}+\mathbf{B}^{(s)}\right)=H(\mathbf{x})
$$

for all $x \in \mathbf{R}^{k}$. Q.E.D.

COROLLARY 2.1. Let $H$ be an extreme value distribution. Then for any $t>0, H^{t}$ is an extreme value distribution.

COROLLARY 2.2. Let $H$ be an extreme value distribution. Then for all $s>0$, there exists vectors $\mathbf{A}^{(s)}>0$ and $\mathbf{B}^{(s)}$ such that (2.1) holds, and if
(a) $H_{i}=\Phi_{\alpha_{i}}, i=1, \cdots, k$, then $A^{(s)}=\left(s^{1 / \alpha_{1}}, \cdots, s^{1 / \alpha_{k}}\right)$ and $\mathbf{B}^{(s)}=0$;
(b) $H_{i}=\Psi_{\alpha_{i}}, i=1, \cdots, k$, then $\mathbf{A}^{(s)}=\left(s^{-1 / \alpha_{1}}, \cdots, s^{-1 / \alpha_{k}}\right)$ and $\mathbf{B}^{(s)}=0$;
(c) $H_{i}=\Lambda, i=1, \cdots, k$, then $A^{(s)}=1=(1, \cdots, 1)$ and $B^{(s)}=(\log s, \cdots, \log s)$, where $\alpha_{i}>0, i=1, \cdots, k$.

EXAMPLE. (See Galambos [7], p.254.) The distribution function

$$
H\left(x_{1}, x_{2}, \cdots, x_{k}\right)=\exp \left\{-\exp \left[-\min \left(x_{1}, x_{2}, \cdots, x_{k}\right)\right]\right\}
$$

is an extreme value distribution (with $H_{i}=\Lambda, i=1, \cdots, k$ ), since for all $s>0$

$$
H^{s}\left(x_{1}+\log s, \cdots, x_{k}+\log s\right)=H\left(x_{1}, \cdots, x_{k}\right)
$$

On the other hand, the distribution function

$$
H\left(x_{1}, x_{2}\right)=\Lambda\left(x_{1}\right) \Lambda\left(x_{2}\right)\left[1+\left(1-\Lambda\left(x_{1}\right)\right)\left(1-\Lambda\left(x_{2}\right)\right) / 2\right]
$$

is not an extreme value distribution, since

$$
\begin{aligned}
H^{s}\left(x_{1}+\log s, x_{2}+\log s\right) & =\Lambda\left(x_{1}\right) \Lambda\left(x_{2}\right)\left[1+\left(1-\Lambda^{1 / s}\left(x_{1}\right)\right)\left(1-\Lambda^{1 / s}\left(x_{2}\right)\right) / 2\right]^{s} \\
& \neq H\left(x_{1}, x_{2}\right)
\end{aligned}
$$

COROLLARY 2.3. (Lemma 5.4.1 of Galambos. [7].) Let $H$ be an extreme value distribution and denote by $D_{H}(\mathbf{y})=H\left(H_{1}^{-1}\left(y_{1}\right), \cdots, H_{k}^{-1}\left(y_{k}\right)\right), \mathbf{y} \varepsilon(0,1)^{k}$, its dependence function. Then $D_{H}$ satisfies for all $s>0$

$$
D_{H}^{s}\left(\mathbf{y}^{1 / s}\right)=D_{H}(\mathbf{y})
$$

LEMMA 2.1. Let $H$ be an extreme value distribution and $D_{H}$ be the dependence function of $H$. If there exists a real number $c \varepsilon(0,1)$ such that

$$
\begin{equation*}
D_{H}(\mathbf{y})=y_{1} y_{2} \cdots y_{k} \quad \text { for all } \mathbf{y} \varepsilon(c, 1)^{k} \tag{2.4}
\end{equation*}
$$

then

$$
D_{H}(\mathbf{y})=y_{1} y_{2} \cdots y_{k} \quad \text { for all } \mathbf{y} \varepsilon(0,1)^{k}
$$

PROOF. For any $\mathbf{y} \varepsilon(0,1)^{k}$, there exists an $s>0$ such that $\mathbf{y}^{1 / s} \varepsilon(c, 1)^{k}$. Hence by Corollary 2.3 and (2.4)

$$
\begin{aligned}
D_{H}(\mathbf{y}) & =\left(D_{H}\left(\mathbf{y}^{1 / s}\right)\right)^{s}=\left(y_{1}^{1 / s} y_{2}^{1 / s} \cdots y_{k}^{1 / s}\right)^{s} \\
& =y_{1} y_{2} \cdots y_{k}
\end{aligned}
$$

for all $y \in(0,1)^{k}$. Q.E.D.

Lemma 2.2. Let $H$ be an extreme value distribution. Let $1 \leq i_{1}<i_{2}$ $<\cdots<i_{m} \leq k, 1 \leq j_{1}<j_{2}<\cdots<j_{k-m} \leq k$ and $\left\{i_{1}, i_{2}, \cdots, i_{m}\right\} \cap\left\{j_{1}, j_{2}, \cdots, j_{k-m}\right\}=\phi$. Then it holds that

$$
\begin{align*}
H\left(x_{1}, x_{2}, \cdots, x_{k}\right) \geq & H_{i_{1} i_{2} \cdots i_{m}}\left(x_{i_{1}}, x_{i_{2}}, \cdots, x_{i_{m}}\right)  \tag{2.5}\\
& \times H_{j_{1} j_{2}} \cdots j_{k-m}\left(x_{j_{1}}, x_{j_{2}}, \cdots, x_{j_{k-m}}\right)
\end{align*}
$$

for all $\times \varepsilon \mathbf{R}^{k}$.
PROOF. Since $H$ is an extreme value distribution, there exist $\mathbf{a}^{(n)}>0$ and $\mathbf{b}^{(n)}$ such that

$$
H^{n}\left(\mathbf{a}^{(n)} \mathbf{x}+\mathbf{b}^{(n)}\right)=H(\mathbf{x})
$$

(see Theorem 2.1). It is easily seen that

$$
\begin{aligned}
& 1-H\left(\mathbf{a}^{(n)} \mathbf{x}+\mathbf{b}^{(n)}\right) \\
& \leq\left\{1-H_{i_{1} i_{2} \cdots i_{m}}\left(a_{i_{1}}^{(n)} x_{i_{1}}+b_{i_{1}}^{(n)}, \cdots, a_{i_{m}}^{(n)} x_{i_{m}}+b_{i_{m}}^{(n)}\right)\right\} \\
&+\left\{1-H_{j_{1} j_{2} \cdots j_{k-m}}\left(a_{j_{1}}^{(n)} x_{j_{1}}+b_{j_{1}}^{(n)}, \cdots, a_{j_{k-m}}^{(n)} x_{j_{k-m}}+b_{j_{k-m}}^{(n)}\right)\right\} \\
&-34-
\end{aligned}
$$

Thus, by Lemma 1.1 it holds that

$$
\begin{aligned}
-\log H(\mathbf{x}) & \leq-\log H_{i_{1} i_{2}} \cdots i_{m}\left(x_{i_{1}}, \cdots, x_{i_{m}}\right) \\
& -\log H_{j_{1} j_{2}} \cdots j_{k-m}\left(x_{j_{1}}, \cdots, x_{j_{k-m}}\right)
\end{aligned}
$$

Hence we have (2.5). Q.E.D.

COROLLARY 2.4. (Theorem 5.4.1 of Galambos [7]). Let $H$ be an extreme value distribution, then we have

$$
H(\mathbf{x}) \geq H_{1}\left(x_{1}\right) H_{2}\left(x_{2}\right) \cdots H_{k}\left(x_{k}\right)
$$

for all $\mathbf{x}=\left(x_{1}, x_{2}, \cdots, x_{k}\right) \in \mathbf{R}^{k}$.

Now we have the following results which characterize the multivariate extreme value distributions.

THEOREM 2.2. Let $H$ be an extreme value distribution. Then it holds either

$$
H(\mathbf{x})=H_{1}\left(x_{1}\right) H_{2}\left(x_{2}\right) \cdots H_{k}\left(x_{k}\right) \quad \text { for all } \mathbf{x} \in \mathbf{R}^{k}
$$

or

$$
H(\mathbf{x})>H_{1}\left(x_{1}\right) H_{2}\left(x_{2}\right) \cdots H_{k}\left(x_{k}\right) \quad \text { for all } \mathbf{x}
$$

such that $0<H_{i}\left(x_{i}\right)<1, i=1,2, \cdots, k$.

This theorem is trivial from the next one. We only prove the latter.

THEOREM 2.3. Let $H$ be an extreme value distribution. Then

$$
\begin{equation*}
H(\mathbf{x})=H_{1}\left(x_{1}\right) H_{2}\left(x_{2}\right) \cdots H_{k}\left(x_{k}\right) \quad \text { for all } \mathbf{x} \in \mathbf{R}^{k} \tag{2.6}
\end{equation*}
$$

if and only if there exists $\mathbf{p}=\left(p_{1}, p_{2}, \cdots, p_{k}\right) \varepsilon \mathbf{R}^{k}$ such that $0<H_{i}\left(p_{i}\right)<1, i=1,2, \cdots, k$ and

$$
\begin{equation*}
H(\mathrm{p})=H_{1}\left(p_{1}\right) H_{2}\left(p_{2}\right) \cdots H_{k}\left(p_{k}\right) \tag{2.7}
\end{equation*}
$$

PROOF. Necessity is obvious so that we shall prove sufficiency.
First we show that

$$
\begin{equation*}
H_{i j}\left(p_{i}, p_{j}\right)=H_{i}\left(p_{i}\right) H_{j}\left(p_{j}\right) \quad \text { for any } i<j \tag{2.8}
\end{equation*}
$$

By Corollary 2.4 it holds that

$$
H_{i j}\left(p_{i}, p_{j}\right) \geq H_{i}\left(p_{i}\right) H_{j}\left(p_{j}\right) \quad \text { for any } i<j
$$

Suppose (2.8) does not hold, i.e., if for example for $i=1$ and $j=2$

$$
H_{12}\left(p_{1}, p_{2}\right)>H_{1}\left(p_{1}\right) H_{2}\left(p_{2}\right)
$$

then by Lemma 2.2 and Corollary 2.4 we have

$$
\begin{aligned}
H\left(p_{1}, p_{2}, \cdots, p_{k}\right) & \geq H_{12}\left(p_{1}, p_{2}\right) H_{34} \cdots k\left(p_{3}, \cdots, p_{k}\right) \\
& >H_{1}\left(p_{1}\right) H_{2}\left(p_{2}\right) H_{3}\left(p_{3}\right) \cdots H_{k}\left(p_{k}\right)
\end{aligned}
$$

This contradicts (2.7), thus we have (2.8). By Lemma 1.1 and (2.8) we have

$$
\begin{align*}
\lim _{n \rightarrow \infty} & n\left\{1-H_{i j}\left(a_{i}^{(n)} p_{i}+b_{i}^{(n)}, a_{j}^{(n)} p_{j}+b_{j}^{(n)}\right)\right\}  \tag{2.9}\\
= & -\log H_{i j}\left(p_{i}, p_{j}\right)=-\log H_{i}\left(p_{i}\right)-\log H_{j}\left(p_{j}\right)
\end{align*}
$$

where $a \underset{l}{(n)}$ and $b_{l}^{(n)}$ are normalizing constants of $H_{l}, l=i, j$. It holds that

$$
\begin{gathered}
\bar{H}_{i j}\left(x_{i}, x_{j}\right)=\left\{1-H_{i}\left(x_{i}\right)\right\}+\left\{1-H_{j}\left(x_{j}\right)\right\} \\
-\left\{1-H_{i j}\left(x_{i}, x_{j}\right)\right\} .
\end{gathered}
$$

Thus, by Lemma 1.1 and (2.9), we have

$$
\lim _{n \rightarrow \infty} n \bar{H}_{i j}\left(a_{i}^{(n)} p_{i}+b \underset{i}{(n)}, a_{j}^{(n)} p_{j}+b \underset{j}{(n)}\right)=0
$$

From the definition of $\bar{H}_{i j}$ and the inequalities $a_{i}^{(n)}, a_{j}^{(n)}>0$ it holds that

$$
\bar{H}_{i j}\left(a_{i}^{(n)} p_{i}+b_{i}^{(n)}, a_{j}^{(n)} p_{j}+b_{j}^{(n)}\right) \geq \bar{H}_{i j}\left(a_{i}^{(n)} x_{i+}{\left.\underset{i}{(n)}, a_{j}^{(n)} x_{j+} b_{j}^{(n)}\right)}^{(n)}\right.
$$

for all $\left(x_{i}, x_{j}\right) \geq\left(p_{i}, p_{j}\right)$. Thus we have

$$
\lim _{n \rightarrow \infty} n \bar{H}_{i j}\left(a_{i}^{(n)} x_{i+} b_{i}^{(n)}, a_{j}^{(n)} x_{j+} b_{j}^{(n)}\right)=0
$$

for any $i<j$. So, by Theorem 1.2 we have

$$
H\left(x_{1}, x_{2}, \cdots, x_{k}\right)=H_{1}\left(x_{1}\right) H_{2}\left(x_{2}\right) \cdots H_{k}\left(x_{k}\right) \quad \text { for all } \mathbf{x} \geq \mathbf{p}
$$

Let $c=\max _{1 \leq i \leq k} H_{i}\left(p_{i}\right)$, then by Lemma 2.1, (2.6) holds for all $\mathbf{x} \varepsilon \mathbf{R}^{k}$. Q.E.D.

REMARK. The proof of this theorem is based on the idea of
Corollary 1.1.

COROLLARY 2.5. (Theorems 2.2, 2.3 and 2.4 of Takahashi [27].) Let $H$ be an extreme value distribution.
(a) Suppose $H_{i}=\Phi_{\alpha_{i}}, \alpha_{i}>0, i=1,2, \cdots, k$. Then

$$
H(\mathbf{x})=\Phi_{\alpha_{1}}\left(x_{1}\right) \Phi_{\alpha_{2}}\left(x_{2}\right) \cdots \Phi_{\alpha_{k}}\left(x_{k}\right) \quad \text { for all } \mathbf{x} \varepsilon \mathbf{R}^{k}
$$

if and only if $H(1)=\Phi_{\alpha_{1}}(1) \Phi_{\alpha_{2}}(1) \cdots \Phi_{\alpha_{k}}(1)$.
(b) Suppose $H_{i}=\Psi_{\alpha_{i}}, \alpha_{i}>0, i=1,2, \cdots, k$. Then

$$
H(\mathbf{x})=\Psi_{\alpha_{1}}\left(x_{1}\right) \Psi_{\alpha_{2}}\left(x_{2}\right) \cdots \psi_{\alpha_{k}}\left(x_{k}\right) \quad \text { for all } \mathbf{x} \varepsilon \mathbf{R}^{k}
$$

if and only if $H(-1)=\Psi_{\alpha_{1}}(-1) \Psi_{\alpha_{2}}(-1) \cdots \Psi_{\alpha_{k}}(-1)$.
(c) Suppose $H_{i}=\Lambda, i=1,2, \cdots, k$. Then

$$
H(x)=\Lambda\left(x_{1}\right) \Lambda\left(x_{2}\right) \cdots \Lambda\left(x_{k}\right) \quad \text { for } a l l \mathbf{x} \in \mathbf{R}^{k}
$$

if and only if $H(0)=\Lambda(0)^{k}$.

### 2.3. Multivariate tail equivalence

In this section, by using Propositions $1.1-1.3$ we extend Theorem 1.7 in Section 1.1 to the multivariate case.

The following theorem is a $k$-dimensional version of Theorem 1.7 (a) in Section 1.1.

THEOREM 3.1. Let $F$ and $G$ be $k$-dimensional distribution functions. Suppose for normalizing vectors $\mathbf{a}^{(n)}>\mathbf{0}, \mathbf{b}^{(n)}, n \geq 1, F^{n}\left(\mathbf{a}^{(n)} \mathbf{x}+\mathbf{b}^{(n)}\right) \rightarrow H(\mathbf{x})$, where $H_{i}=\Phi_{\alpha_{i}}, \alpha_{i}>0, i=1, \cdots, k$. Then

$$
G^{n}\left(\mathbf{a}^{(n)} \mathbf{x}+\mathbf{b}^{(n)}\right) \rightarrow H(\mathbf{A x}+\mathbf{B}), \quad \text { and } \quad \mathbf{A}=\left(c^{1 / \alpha_{1}}, \cdots, c^{1 / \alpha} k\right), c>0
$$

if and only if $\mathbf{B}=\mathbf{0}$ and

$$
\begin{equation*}
\lim _{t \rightarrow \infty} \frac{1-F\left(t x_{1}, \phi_{2}(t) x_{2}, \cdots, \phi_{k}(t) x_{k}\right)}{1-G\left(t x_{1}, \phi_{2}(t) x_{2}, \cdots, \phi_{k}(t) x_{k}\right)}=c \tag{3.1}
\end{equation*}
$$

for all $\mathbf{x}=\left(x_{1}, x_{2}, \cdots, x_{k}\right)$ such that $0<H(\mathbf{x})<1$, where $\phi_{i}(t)=\bar{F}_{i}^{-1} \bar{F}_{1}(t)$, $i=2, \cdots, k$.

PROOF. If $F \in \mathrm{D}(H)$, then it is known that we can take $\mathbf{b}^{(n)}=0, a_{1}^{(n)}$ $=\bar{F}_{1}^{-1}(1 / n)$ and $a_{i}^{(n)}=\bar{F}_{i}^{-1} \bar{F}_{1}\left(a_{1}^{(n)}\right)=\phi_{i}\left(a_{1}^{(n)}\right), i=2, \cdots, k, n \geq 1$ (see Appendix I).

Sufficiency. Since $a_{1}^{(n)} \rightarrow \infty$ as $n+\infty$ and (3.1), we have that for all $x$ such that $0<H(\mathbf{x})<1$,

$$
\begin{aligned}
c & =\lim _{n \rightarrow \infty} \frac{1-F\left(a_{1}^{(n)} x_{1}, \phi_{2}\left(a_{1}^{(n)}\right) x_{2}, \cdots, \phi_{k}\left(a_{1}^{(n)}\right) x_{k}\right)}{1-G\left(a_{1}^{(n)} x_{1}, \phi_{2}\left(a_{1}^{(n)}\right) x_{2}, \cdots, \phi_{k}\left(a_{1}^{(n)}\right) x_{k}\right)} \\
& =\lim _{n \rightarrow \infty} \frac{n\left\{1-F\left(a^{(n)} \mathbf{x}\right)\right\}}{n\left\{1-G\left(a^{(n)} \mathbf{x}\right)\right\}} .
\end{aligned}
$$

Then by Lemma 1.1 and Corollary 2.2 we have

$$
G^{n}\left(\mathbf{a}^{(n)} \mathbf{x}\right) \rightarrow H^{1 / c}(\mathbf{x})=H\left(c^{1 / \alpha_{1}} x_{1}, \cdots, c^{1 / \alpha_{k}} k_{x_{k}}\right)=H(\mathbf{A x})
$$

Necessity. From the univariate result (Theorem 1.7 (a) in Section 1.1), it holds that $B_{i}=0, i=1, \cdots, k$. So we have $B=0$. Since $a_{1}^{(n)} \leq a_{1}^{(n+1)} \rightarrow \infty$, for any sufficiently large $t$ there exists an $n \varepsilon \mathbf{N}$ such that $a_{1}^{(n)} \leq t \leq$ $a_{1}^{(n+1)}$. For any $\mathbf{x}=\left(x_{1}, \cdots, x_{k}\right)$ such that $0<H(\mathbf{x})<1$, we have $0<\mathbf{x} \neq \infty$. Moreover, $\phi_{i}$ is non-decreasing, $i=2, \cdots, k$. Therefore we have

$$
\begin{aligned}
\frac{1-F\left(\mathbf{a}^{(n+1)} \mathbf{x}\right)}{1-G\left(\mathbf{a}^{(n)} \mathbf{x}\right)} & \leq \frac{1-F\left(t x_{1}, \phi_{2}(t) x_{2}, \cdots, \phi_{k}(t) x_{k}\right)}{1-G\left(t x_{1}, \phi_{2}(t) x_{2}, \cdots, \phi_{k}(t) x_{k}\right)} \\
& \leq \frac{1-F\left(\mathbf{a}^{(n)} \mathbf{x}\right)}{1-G\left(\mathbf{a}^{(n+1)} \mathbf{x}\right)}
\end{aligned}
$$

for all $\mathbf{x}$ such that $0<H(\mathbf{x})<1$. Taking the limits of above inequalities, we have (3.1). Q.E.D.

If we consider the particular case $F_{1}=\cdots=F_{k}$, than we have the following handy result.

COROLLARY 3.1. Let $F$ and $G$ be $k$-dimensional distribution functions. Suppose $F_{1}=\cdots=F_{k}$ and that there exist $a^{(n)}>0, b^{(n)}, n \geq 1$ such that $F^{n}\left(a^{(n)} \mathbf{x}+b^{(n)} 1\right)+H(\mathbf{x})$, where $H_{i}=\Phi_{\alpha}, i=1, \cdots, k, \alpha>0$. Then

$$
G^{n}\left(a^{(n)} \mathbf{x}+b^{(n)} 1\right) \rightarrow H(\mathbf{A x}+\mathbf{B}) \text { and } \mathbf{A}=c^{1 / \alpha} \mathbf{1}, c>0
$$

if and only if $\mathbf{B}=\mathbf{0}$ and

$$
\lim _{t \rightarrow \infty} \frac{1-F(t \mathbf{x})}{1-G(t \mathbf{x})}=c \quad \text { for } \text { all } \mathbf{x}
$$

such that $0<H(\mathbf{x})<1$.

Next we establish a $k$-dimensional version of Theorem 1.7 (b) in Section 1.1 which can be proved similarly to Theorem 3.1.

THEOREM 3.2. Let $F$ and $G$ be $k$-dimensional distribution functions and $\mathbf{a}^{(n)}>0, \mathbf{b}^{(n)}, n \geq 1$ are normalizing vectors such that $F^{n}\left(\mathbf{a}^{(n)} \mathbf{x}+\mathbf{b}^{(n)}\right) \rightarrow$ $H(\mathbf{x})$, where $H_{i}=\Psi_{\alpha_{i}}, \alpha_{i}>0, i=1, \cdots, k$. Then

$$
G^{n}\left(\mathbf{a}^{(n)} \mathbf{x}+\mathbf{b}^{(n)}\right)+H(\mathbf{A} \mathbf{x}+\mathbf{B}) \quad \text { and } \quad \mathbf{A}=\left(c^{-1 / \alpha} 1, \ldots, c^{-1 / \alpha} k\right), c>0
$$

if and only if $\mathbf{B}=0, \mathbf{x}_{F}^{0}=\mathbf{x}_{G}^{0}=\mathbf{x}^{0} \varepsilon \mathbf{R}^{\mathcal{k}}$ and

$$
\lim _{t \downarrow 0} \frac{1-F\left(\left(t x_{1}, \phi_{2}(t) x_{2}, \cdots, \phi_{k}(t) x_{k}\right)+\mathbf{x}^{0}\right)}{1-G\left(\left(t x_{1}, \phi_{2}(t) x_{2}, \cdots, \phi_{k}(t) x_{k}\right)+\mathbf{x}^{0}\right)}=c
$$

for all $\mathbf{x}=\left(x_{1}, \cdots, x_{k}\right)$ such that $0<H(\mathbf{x})<1$, where $x_{i}^{0}=x_{F_{i}}^{0} \quad i=1, \cdots, k$. and $\phi_{i}(t)=x_{i}^{0}-\bar{F}_{i}^{-1}\left(\bar{F}_{1}\left(x_{1}^{0}-t\right)\right), i=2, \cdots, k$.

COROLLARY 3.2. Let $F$ and $G$ be $k$-dimensional distribution functions. Suppose $F_{1}=\cdots=F_{k}$ and that there exist $a^{(n)}>0, b^{(n)}, n \geq 1$ such that $F^{n}\left(a^{(n)} \mathbf{x}+b^{(n)} 1\right) \rightarrow H(\mathbf{x})$, where $H_{i}=\Psi_{\alpha}, i=1, \cdots, k, \alpha>0$. Then

$$
G^{n}\left(a^{(n)} \mathbf{x}+b^{(n)} 1\right) \rightarrow H(\mathbf{A x}+\mathrm{B}) \quad \text { and } \quad \mathbf{A}=c^{-1 / \alpha} 1, c>0
$$

if and only if $\mathrm{B}=0, x_{F_{i}}^{0}=x_{G_{i}}^{0}=x^{0} \in \mathrm{R}, i=1, \cdots, k$, and

$$
\lim _{t+0} \frac{1-F\left(t \mathbf{x}+x^{0} 1\right)}{1-G\left(t \mathbf{x}+x^{0} 1\right)}=c \text { for all } \mathbf{x}
$$

such that $0<H(x)<1$.

Finally, we establish a $k$-dimensional version of Theorem 1.7 (c)

```
in Section 1.1.
```

THEOREM 3.3. Let $F$ and $G$ be $k$-dimensional distribution functions, and $\mathbf{a}^{(n)}>\mathbf{0}, \mathbf{b}^{(n)}, n \geq 1$ are normalizing vectors such that $F^{n}\left(\mathbf{a}^{(n)} \mathbf{x}+\mathbf{b}^{(n)}\right)$ + $H(\mathbf{x})$, where $H_{i}=\Lambda, i=1, \cdots, k$. Then

$$
\begin{equation*}
G^{n}\left(\mathbf{a}^{(n)} \mathbf{x}+\mathbf{b}^{(n)}\right) \rightarrow H(\mathbf{A} \mathbf{x}+\mathbf{B}) \text { and } \mathbf{A}>0, \mathbf{B}=b \mathbf{1} \tag{3.2}
\end{equation*}
$$

if and only if $\mathbf{A}=\mathbf{1}, \mathbf{x}_{F}^{0}=\mathbf{x}_{G}^{0}=\mathbf{x}^{0}$ and

$$
\begin{equation*}
\lim _{t \uparrow x_{1}^{0}} \frac{1-F(\mathbf{a}(t) \mathbf{x}+\mathbf{b}(t))}{}=e^{b} \quad \text { for all } \mathbf{x} \tag{3.3}
\end{equation*}
$$

such that $0<H(\mathbf{x})<1$, where $x_{1}^{0}=x_{F_{1}}^{0}, a_{i}(t)=\bar{F}_{i}^{-1}\left(\bar{F}_{1}(t) / e\right)-\bar{F}_{i}^{-1} \bar{F}_{1}(t)$ and $b_{i}(t)=\bar{F}_{i}^{-1} \bar{F}_{1}(t), i=1, \cdots, k$.

PROOF. If $F \in \mathbf{D}(H)$, then we can suppose without loss of generality that

$$
b_{i}^{(n)}=\bar{F}_{i}^{-1} \bar{F}_{1}\left(b_{1}^{(n)}\right)
$$

and

$$
a_{i}^{(n)}=\bar{F}_{i}^{-1}\left(\bar{F}_{1}\binom{(n)}{1} / e\right)-\bar{F}_{i}^{-1} \bar{F}_{1}\left(b_{1}^{(n)}\right), i=1, \cdots, \mathrm{k} .
$$

(See Appendix II.)
Sufficiency. Since $\lim _{n \rightarrow \infty} \underset{1}{(n)}=x_{1}^{0}$ and $\left\{b_{1}^{(n)}\right\}$ is an increasing sequence, by (3.3) we have

$$
\begin{aligned}
e^{b} & =\lim _{n+\infty} \frac{1-F\left(\mathbf{a}\left(b_{1}^{(n)}\right) \mathbf{x}+\mathbf{b}\left(b_{1}^{(n)}\right)\right)}{1-G\left(\mathbf{a}\left(b_{1}^{(n)}\right) \mathbf{x}+\mathbf{b}\left(b_{1}^{(n)}\right)\right)} \\
& =\lim _{n \rightarrow \infty} \frac{n\left\{1-F\left(\mathbf{a}^{(n)} \mathbf{x}+\mathbf{b}^{(n)}\right)\right\}}{n\left\{1-G\left(\mathbf{a}^{(n)} \mathbf{x}+\mathbf{b}^{(n)}\right)\right\}} .
\end{aligned}
$$

Hence by Lemma 1.1 and Corollary 2.2 we have

$$
G^{n}\left(\mathbf{a}^{(n)} \mathbf{x}+\mathbf{b}^{(n)}\right)+H^{1 / e^{b}}(\mathbf{x})=H(\mathbf{x}+\mathbf{B}), \text { where } \mathbf{B}=b \mathbf{1}
$$

Necessity. Consider the marginal distributions $F_{i}, G_{i}$ and $H_{i}=\Lambda, i=1$, $\cdots, k$, then by Theorem 1.7 (c) in Section 1.1 , we have $\mathbf{A}=\mathbf{1}$ and $\mathbf{x}_{F}^{0}=\mathbf{x}_{G}^{0}=\mathbf{x}^{0}$. Proposition 1.3 implies

$$
\begin{equation*}
\lim _{t \uparrow x_{1}^{0}} \frac{1-F(\mathbf{a}(t) \mathbf{x}+\mathbf{b}(\dot{t}))}{1-F_{1}(t)}=-\log H(\mathbf{x}) \text { for all } \mathbf{x} \text { such that } \tag{3.4}
\end{equation*}
$$ $0<H(\mathbf{x})<1$. Now we shall prove that for all $\mathbf{x}$ such that $0<H(\mathbf{x})<1$

$$
\begin{equation*}
\lim _{t+x_{1}^{0}} \frac{1-G(\mathbf{a}(t) \mathbf{x}+\mathbf{b}(t))}{1-F_{1}(t)}=-e^{-b} \log H(\mathbf{x}) \tag{3.5}
\end{equation*}
$$

From (3.2) and $\mathbf{A}=\mathbf{1}$, we have $G^{n}\left(\mathbf{a}^{(n)} \mathbf{x}+\mathbf{b}^{(n)}\right) \rightarrow H^{e^{-b}}(\mathbf{x})$. So it holds

$$
\lim _{s \rightarrow \infty} s\{1-G(\alpha(s) \mathbf{x}+\boldsymbol{\beta}(s))\}=-e^{-b} \log H(\mathbf{x})
$$

where $\alpha_{i}(s)=\bar{F}_{i}^{-1}(1 /(e s))-\bar{F}_{i}^{-1}(1 / s)$ and $\beta_{i}(s)=\bar{F}_{i}^{-1}(1 / s), i=1, \cdots, k$. (This result can be proved similarly to Theorem 1.3 (e) in Section 1.1.) Now, let $s(t)=1 /\left(1-F_{1}(t)\right)$, then $\alpha(s(t))=\mathbf{a}(t)$ and $\boldsymbol{B}(s(t))=\mathbf{b}(t)$, thus we have (3.5). The relations (3.4) and (3.5) imply (3.3). Q.E.D.

COROLLARY 3.3. Let $F$ and $G$ be $k$-dimensional distribution functions. Suppose $F_{1}=\cdots=F_{k}$ and that there exist $a^{(n)}>0, b^{(n)}, n \geq 1$ such that $F^{n}\left(a^{(n)} \mathbf{x}+b^{(n)} \mathbf{1}\right) \rightarrow H(\mathbf{x})$, where $H_{i}=\Lambda, i=1, \cdots, k$. Then

$$
G^{n}\left(a^{(n)} \mathbf{x}+b^{(n)} 1\right)+H(\mathbf{A x}+\mathbf{B}) \quad \text { and } \mathbf{A}>0, \mathbf{B}=b \mathbf{1}
$$

if and only if $A=1, x_{F_{i}^{0}}^{0}=x_{G_{i}}^{0}=x^{0}, i=1, \cdots, k$ and

$$
\lim _{t+x^{0}} \frac{1-F(a(t) \mathbf{x}+t 1)}{1-G(a(t) \mathbf{x}+t 1)}=e^{b} \quad \text { for } a l l \mathbf{x}
$$

such that $0<H(\mathbf{x})<1$, where $a(t)=\bar{F}_{1}^{-1}\left(\bar{F}_{1}(t) / e\right)-t$.

### 2.4. Examples

In this section, some examples concerning the multivariate tail equivalence are shown.

First we consider an application of the multivariate tail equivalence to the limit distribution of an extreme statistic from a bivariate exponential distribution.

Let $\left(X_{1}, X_{2}\right)$ be two-dimensional random vector, where $X_{1}$ and $X_{2}$ are unit exponential variate. Let $F\left(x_{1}, x_{2}\right)$ be their bivariate distribution function. We put

$$
\bar{F}\left(x_{1}, x_{2}\right)=P\left(X_{1}>x_{1}, X_{2}>x_{2}\right) .
$$

Then

$$
\begin{equation*}
F\left(x_{1}, x_{2}\right)=1-e^{-x_{1}}-e^{-x_{2}}+\bar{F}\left(x_{1}, x_{2}\right) . \tag{4.1}
\end{equation*}
$$

Versions of the following theorem have been obtaind by Galambos [7] and Marshall and Olkin [14]; it has a simple direct proof.

THEOREM 4.1. Let $F$ be a distribution function defined in (4.1). Then

$$
F \in \mathrm{D}(H) \text { and } H\left(x_{1}, x_{2}\right)=\Lambda\left(x_{1}\right) \Lambda\left(x_{2}\right)
$$

if and only if

$$
\begin{equation*}
\lim _{s \rightarrow \infty} s \bar{F}\left(x_{1}+\log s, x_{2}+\log s\right)=0 \tag{4.2}
\end{equation*}
$$

PROOF. Let

$$
F_{0}\left(x_{1}, x_{2}\right)=1-e^{-x_{1}}-e^{-x_{2}}+e^{-x_{1}} e^{-x_{2}}=\left(1-e^{-x_{1}}\right)\left(1-e^{-x_{2}}\right)
$$

Then $F_{0} \in \mathbf{D}(H)$. By Corollary 3.3, $F \in \mathbf{D}(H)$ if and only if

$$
\begin{equation*}
\lim _{t \rightarrow \infty} \frac{1-F\left(x_{1}+t, x_{2}+t\right)}{1-F_{0}\left(x_{1}+t, x_{2}+t\right)}=1 . \tag{4.3}
\end{equation*}
$$

Then it is easy to see that (4.3) holds if and only if (4.2) holds. Q.E.D.

EXAMPLE 4.1. (See Galambos [7], p.247.) The Morgenstern distribution

$$
\bar{F}\left(x_{1}, x_{2}\right)=e^{-x_{1}-x_{2}}\left[1+\alpha\left(1-e^{-x_{1}}\right)\left(1-e^{-x_{2}}\right)\right],
$$

where $-1 \leq \alpha \leq 1$, satisfies (4.2). The Marshall-Olkin distribution

$$
\bar{F}\left(x_{1}, x_{2}\right)=\exp \left[-x_{1}-x_{2}-\lambda \max \left(x_{1}, x_{2}\right)\right] \text {, where } \lambda>0 \text {, }
$$

satisfies (4.2). On the other hand, the Mardia's distribution

$$
\bar{F}\left(x_{1}, x_{2}\right)=\left(e^{x_{1}}+e^{x_{2}}-1\right)^{-1}
$$

does not satisfy (4.2). Therefore, the Morgenstern and the Marshall-0lkin distribution belongs to $\mathrm{D}(H)$, but the Mardia's distribution does not belong to $\mathrm{D}(H)$, where $H\left(x_{1}, x_{2}\right)=\Lambda\left(x_{1}\right) \Lambda\left(x_{2}\right)$ for all $\left(x_{1}, x_{2}\right) \in \mathbf{R}^{2}$.

Note that in general univariate tail equivalence does not imply the multivariate tail equivalence as the following counter-example shows.

EXAMPLE 4.2. Consider the following two distribution functions.

$$
F\left(x_{1}, x_{2}\right)=H\left(x_{1}\right) H\left(x_{2}\right) \quad \text { and } \quad G\left(x_{1}, x_{2}\right)=H\left(\min \left(x_{1}, x_{2}\right)\right),
$$

where $H$ is an univariate extreme value distribution.
(a) If $H=\Phi_{\alpha}$, then

$$
F^{n}\left(n^{1 / \alpha_{x_{1}}, n^{1 / \alpha}} x_{2}\right)=F\left(x_{1}, x_{2}\right) \quad \text { and } \quad G^{n}\left(n^{1 / \alpha_{1}} x_{1} n^{1 / \alpha_{2}} x_{2}\right)=G\left(x_{1}, x_{2}\right)
$$

But it does not hold that

$$
\lim _{t \rightarrow \infty} \frac{1-F\left(x_{1}, x_{2}\right)}{1-G\left(x_{1}, x_{2}\right)}=1 \quad \text { for all } x_{1}, x_{2}>0
$$

(b) If $H=\Psi_{\alpha}$, then

$$
F^{n}\left(n^{-1 / \alpha} x_{1}, n^{-1 / \alpha} x_{2}\right)=F\left(x_{1}, x_{2}\right) \text { and } G^{n}\left(n^{-1 / \alpha} x_{1}, n^{-1 / \alpha} x_{2}\right)=G\left(x_{1}, x_{2}\right)
$$

But it does not hold that

$$
\lim _{t+0} \frac{1-F\left(t x_{1}, t x_{2}\right)}{1-F\left(t x_{1}, t x_{2}\right)}=1 \quad \text { for all } x_{1}, x_{2}<0
$$

(c) If $H=\Lambda$, then

$$
F^{n}\left(x_{1}+\log n, x_{2}+\log n\right)=F\left(x_{1}, x_{2}\right)
$$

and

$$
G^{n}\left(x_{1}+\log n, x_{2}+\log n\right)=G\left(x_{1}, x_{2}\right)
$$

But it does not hold that

$$
\lim _{t \rightarrow \infty} \frac{1-F\left(x_{1}+t, x_{2}+t\right)}{1-G\left(x_{1}+t, x_{2}+t\right)}=1 \quad \text { for all }\left(x_{1}, x_{2}\right) \in \mathbf{R}^{2}
$$

## Appendix I

By Lemma 0.2 in Chapter 0 it is sufficient to prove
(A.1) $\quad \lim _{n \rightarrow \infty} \frac{\bar{F}_{i}^{-1}(1 / n)}{\bar{F}_{i}^{-1}\left(\bar{F}_{1}\binom{(n)}{1}\right)}=1, \quad i=2, \cdots, k$.

The relation

$$
\lim _{n \rightarrow \infty} \frac{n}{1 / \bar{F}_{1}\left(a_{( }^{(n)}\right)}=\lim _{n \rightarrow \infty} n\left\{1-F_{1}\binom{(n)}{1}\right\}=1
$$

holds. Hence by Theorem 1.1 in Section 1.1 and Theorem 0.1 (b), (c) in Chapter 0 we have (A.1).

## Appendix II

It is sufficient to prove

$$
\begin{equation*}
F_{i}^{n}\left(a_{i}^{(n)} x+b \underset{i}{(n)}\right) \rightarrow \Lambda(x) \tag{A.2}
\end{equation*}
$$

where $a_{i}^{(n)}=\bar{F}_{i}^{-1}\left(\bar{F}_{1}\binom{(n)}{1} / e\right)-\bar{F}_{i}^{-1} \bar{F}_{1}\binom{(n)}{1}$ and $b_{i}^{(n)}=\bar{F}_{i}^{-1} \bar{F}_{1}\left(b \begin{array}{c}(n)\end{array}\right), i=2, \cdots, k$.
Since the relation

$$
\lim _{n \rightarrow \infty} n \bar{F}_{1}\binom{(n)}{1}=1
$$

holds, we obtain

$$
\begin{aligned}
& \lim _{n \rightarrow \infty}\left\{1-\bar{F}_{1}\binom{(n)}{1}\right\}^{n}=e^{-1} \\
& \lim _{n \rightarrow \infty}\left\{1-\bar{F}_{1}\binom{(n)}{1} / e\right\}^{n}=e^{-e^{-1}}
\end{aligned}
$$

Hence by Theorem 0.2 in Chapter 0 we have (A.2).

## CHAPTER 3 <br> OUTLIER-PRONE AND OUTLIER-RESISTANT DISTRIBUTIONS

### 3.1. Introduction

In this chapter we consider an application of the distribution theory of order statistics to a problem of outliers.

Let $S_{n}$ be a sample of size $n$ of independent observations of random variables with common distribution function $F$. In the following we only consider distribution functions with endpoint at infinity. Let the variable values be denoted by $X_{1}, X_{2}, \cdots, X_{n}$ and let the ordered values be $X_{n 1}, X_{n 2}, \cdots, X_{n n}$. For a positive number $k$, Neyman and Scott [17] called $X_{n n}$ a $k$-outlier if $X_{n n}-X_{n n-1}>k\left(X_{n n-1}-X_{n 1}\right)$. Let $P(k, n \mid F)$ denote the probability that a sample $S_{n}$ of observations from a distribution $F$ will contain a $k$-outlier. Let $F$ be a family of distributions and let $\pi(k, n \mid F)$ stand for the least upper bound of probabilities $P(k, n \mid F)$ for $F \in F$. Then Neyman and Scott [17] offered the following definitions of outlierproneness and outlier-resistance of a family of distributions.

DEFINITION 1.1. If $\Pi(k, n \mid F)<1$ then we shall say that the family $\boldsymbol{F}$ is ( $k, n$ )-outlier-resistant. Otherwise, that is, if $\pi(k, n \mid F)=1$, we shall say that the family $F$ is $(k, n)$-outlier-prone.

DEFINITION 1.2. If a family of distributions $F$ is ( $k, n$ )-outlier-prone for all $k>0$ and all $n>2$, we shall say that $F$ is outlier-prone completely.

REMARK 1.1. Green [9] showed that the family of distributions $F$ is outlier-prone completely if and only if it is $(k, n)$-outlier-prone for some $k>0, n>2$.

Neyman and Scott [17] showed the following lemmas.

LEMMA 1.1. If a family $F$ is composed of distributions $F(x / \sigma)$ that differ only in the scale parameter $\sigma>0$, then the probability $P(k, n \mid \sigma)$ $=P(k, n \mid 1)$ and for any $k>0$ and $n>2$, the family $F$ is outlier-resistant.

LEMMA 1.2. If a family $F$ is composed of distributions $F(x-\xi)$ that differ only in their location parameter, $\xi$, then $P(k, n \mid \xi)=P(k, n \mid 0)$ and for any $k>0$ and $n>2$, the family $F$ is outlier-resistant.

Neyman and Scott [17] mentioned the following:
The two lemmas imply that the family $N\left(\xi, \sigma^{2}\right)$ of normal distributions (with mean $\xi$ and variance $\sigma^{2}$ ) is outlier-resistant. Also, perhaps unexpectedly, the family $C(\xi, \sigma)$ of Cauchy distributions (centered at $\xi$ and having scale parameter $\sigma$ ) is outlier-resistant.

Neyman and Scott [17] proved the following two theorems.

THEOREM 1.1. The family of Garma distributions is outlier-prone completely.

THEOREM 1.2. The family of lognormal distributions is outlier-prone completely.

In Section 3.2 we show that the family of Weibull distributions is outlier-prone completely.

On the other hand, Green [10] considered the ideas of outlierproneness and outlier-resistance of individual distributions, introducing the following definitions.

DEFINITION 1.3. A distribution $F$ will be said to be absolutely outlier-resistant (notation $F \in\{A O R\}$ ) if, for all $\varepsilon>0$, we have

$$
P\left(X_{n n}-X_{n n-1}>\varepsilon\right) \rightarrow 0 \quad \text { as } n \rightarrow \infty
$$

DEFINITION 1.4. A distribution $F$ will be said to be relatively outlier-resistant (notation $F \in\{R O R\}$ ) if, for all $k>1$, we have

$$
P\left(X_{n n} / X_{n n-1}>k\right) \rightarrow 0 \text { as } n \rightarrow \infty
$$

DEFINITION 1.5. A distribution $F$ will be said to be absolutely outlier-prone (notation $F \varepsilon\{A O P\}$ ) if there exist constants $\varepsilon>0$, $\delta>0$ and an integer $n_{0}$ such that

$$
P\left(X_{n n}-X_{n n-1}>\varepsilon\right) \geq \delta \text { for all integers } n \geq n_{0}
$$

DEFINITION 1.6. A distribution $F$ will be said to be relatively outlier-prone (notation $F \in\{$ ROP\}) if there exist constants $k>1$, $\delta>0$ and an integer $n_{0}$ such that

$$
P\left(X_{n n} / X_{n n-1}>k\right) \geq \delta \quad \text { for all integers } n \geq n_{0}
$$

Green [10] showed the following theorem connecting the definitions of outlier-proneness and outlier-resistance to the classical laws of large numbers for maxima and relative stability for maxima given by Gnedenko [8].

THEOREM 1.3. Let $F$ be a distribution function, then
(a) $F \in\{A O R\}$ iff for all $\varepsilon>0$
$\lim _{x \rightarrow \infty}[1-F(x+\varepsilon)] /[1-F(x)]=0 ;$
(b) $F \in\{R O R\}$ iff for all $k>1$
$\lim [1-F(k x)] /[1-F(x)]=0 ;$
$x^{+\infty}$
(c) $F \in\{A O P\}$ iff there exist constants $\alpha>0$ and $B>0$ such that

$$
[1-F(x+\beta)] /[1-F(x)] \geq \alpha \quad \text { for all finite } x ;
$$

(d) $F \in\{R O P\} \quad$ iff there exist constants $k>1$ and $\delta>0$ such that $[1-F(k x)] /[1-F(x)] \geq \delta \quad$ for all finite $x$.

Green [10] also showed the following theorem.

THEOREM 1.4. Suppose the distribution function $F$ has a density $f$.
(a) If
(A)

$$
f(x+\varepsilon) / f(x) \rightarrow 0 \text { as } x \rightarrow \infty \quad \text { for all } \varepsilon>0,
$$

then $F \in\{A O R\}$.
If $f$ has a monotone right tail and $F \in\{A O R\}$, then (A) holds.
(b) If
(B)

$$
f(k x) / f(x) \rightarrow 0 \text { as } x \rightarrow \infty \text { for all } k>1,
$$

then $F \in\{R O R\}$.
If $f$ has a monotone right tail and $F \varepsilon\{R O R\}$, then (B) holds.
(c) If there exist constants $\varepsilon>0, \delta>0, x_{0}$ such that

$$
f(x+\varepsilon) / f(x) \geq \delta \quad \text { for all } x \geq x_{0}
$$

then $F \in\{A O P\}$.
(d). If there exist constants $k>1, \delta>0, x_{0}$ such that

$$
f(k x) / f(x) \geq \delta \quad \text { for all } x \geq x_{0}
$$

then $F \in\{$ ROP\}.

In Section 3.3 some properties of outlier-proneness and outlierresistance are established. In Section 3.4 examples of outlier-prone and outlier-resistant distributions are given.

### 3.2. Outlier properties of the family of Weibull distributions

For $\sigma>0, \alpha>0$ and $\xi$, we say that a random variable $X$ follows a Weibull distribution if its distribution function is given by

$$
W(x)= \begin{cases}1-\exp \left\{-((x-\xi) / \sigma)^{\alpha}\right\}, & \text { for } x>\xi \\ 0, & \text { otherwise }\end{cases}
$$

Because of Lemmas 1.1 and 1.2 , in investigating the outlier properties of the Weibull distributions, we may restrict ourselves to the case $\xi=0$ and $\sigma=1$.

The weibull distribution function, depending upon a shape parameter $\alpha>0$, will be denoted by $W(x \mid \alpha)$. The corresponding density will be

$$
w(x \mid \alpha)= \begin{cases}\alpha x^{\alpha-1} \exp \left(-x^{\alpha}\right), & \text { for } x>0 \\ 0, & \text { otherwise }\end{cases}
$$

THEOREM 2.1. The family of Weibull distributions is outlier-prone completely.

PROOF. The proof of this theorem is based on the same device as that of Theorem 1.1 (see Neyman and Scott [17] (pp. 416-417)).

Let $Q(k, n \mid \alpha)$ denote the probability that the largest of the $n$ sample menbers will exceed the next largest by more than a factor $k+1$. Then the probability $P(k, n \mid \alpha)$ of a $k$-outlier in a sample of $n$ will satisfy

$$
1>P(k, n \mid \alpha)>Q(k, n \mid \alpha)
$$

where

$$
Q(k, n \mid \alpha)=n \int_{0}^{\infty} W^{n-1}(x /(k+1) \mid \alpha) w(x \mid \alpha) d x .
$$

For any $k>0$ and any $n>2$, it holds that

$$
\begin{aligned}
Q(k, n \mid \alpha) & =n \int_{0}^{\infty}\left(1-e^{-(x /(k+1))^{\alpha}}\right)^{n-1} \alpha x^{\alpha-1} e^{-x^{\alpha}} d x \\
& =n \int_{0}^{\infty}\left(1-e^{-y /(k+1)^{\alpha}}\right)^{n-1} e^{-y} d y \\
& >n \int_{0}^{T}\left(1-e^{-y /(k+1)^{\alpha}}\right)^{n-1} e^{-y} d y \quad \text { for any } T>0 \\
& +\left(1-e^{-T}\right)^{n} \quad \text { as } \alpha \rightarrow 0 .
\end{aligned}
$$

Thus we have that

$$
P(k, n \mid \alpha)>Q(k, n \mid \alpha) \rightarrow 1 \quad \text { as } \alpha+0 .
$$

Q.E.D.

### 3.3. Properties of outlier-prone and outlier-resistant distributions

In this section we establish some properties of outlier-prone and outlier-resistant distributions defined by Green [10] (see Definitions 1.3-1.6).

Following results are seen in Green [10].

PROPOSITION 3.1. Let $F$ be a distribution function.
(a) If $F \in\{\mathrm{AOR}\}$, then $F \in\{\mathrm{ROR}\}$.
(b) If $F \in\{R O P\}$, then $F \in\{A O P\}$.
(c) $\{R O R\} \cap\{R O P\}=\phi$.
(d) $\{A O R\} \cap\{A O P\}=\phi$.

PROPOSITION 3.2. Let $F$ be a distribution function with infinite endpoint. Then $F$ belongs to one of the following disjoint classes:

```
Class I = {AOR},
Class III = {AOP} \bigcap{ROR},
Class V = {ROP}
```

Class $I I=\{R O R\} \cap\{A O R\}^{c} \cap\{A O P\}^{c}$,
Class $I V=\{A O P\} \cap\{R O R\}^{c} \cap\{R O P\}^{c}$,
Class VI $=\{R O R\}^{c} \cap\{A O P\}^{c}$.

Now we have the following theorem.

THEOREM 3.1. Let $F$ and $G$ be distribution functions and the function $R: \mathbf{R}^{\boldsymbol{+}} \rightarrow \mathbf{R}^{\boldsymbol{+}}$ defined by

$$
R(x)=[1-F(x)] /[1-G(x)]
$$

is $\rho$-varying at infinity, where $\rho \varepsilon \mathbf{R}$ and $\mathbf{R}^{+}=(0, \infty)$. Then
(a) $F \in\{A O R\}$ iff $G \in\{A O R\} ;$
(b) $F \in\{\mathrm{ROR}\}$ iff $G \varepsilon\{\mathrm{ROR}\}$;
(c) $F \in\{A O P\} \quad$ iff $G \varepsilon\{A O P\}$;
(d) $F \in\{$ ROP $\} \quad$ iff $G \in\{R O P\}$.

PROOF. By assumption of $R(x)$, we have

$$
\begin{equation*}
\lim _{x \rightarrow \infty} R(x+\varepsilon) / R(x)=1 \quad \text { for all } \varepsilon>0 \tag{3.1}
\end{equation*}
$$

and

$$
\begin{equation*}
\lim _{x \rightarrow \infty} R(k x) / R(x)=k^{\rho} \quad \text { for all } k>1 \tag{3.2}
\end{equation*}
$$

( By Theorem 0.1 (a) in Chapter 0, it is easy to show (3.1).)
(a) Suppose $G \varepsilon\{A O R\}$. By Theorem 1.3.(a), for all $\varepsilon>0$

$$
[1-G(x+\varepsilon)] /[1-G(x)]+0 \quad \text { as } x+\infty
$$

Thus, by (3.1), for all $\varepsilon>0$

$$
\frac{1-F(x+\varepsilon)}{1-F(x)}=\frac{R(x+\varepsilon)}{R(x)} \cdot \frac{1-G(x+\varepsilon)}{1-G(x)}+0 \quad \text { as } x+\infty
$$

Therefore, by Theorem 1.3 (a) it holds that $F \varepsilon\{A O R\}$.
Similarly, we can prove the converse.
(b) The proof is analogous to that of part (a).
(c) Suppose $G \in\{$ AOP\}. By Theorem 1.3 (c) there exist $\alpha>0$ and $B>0$ such that

$$
[1-G(x+\beta)] /[1-G(x)] \geq \alpha \quad \text { for all finite } x
$$

On the other hand,

$$
\frac{1-F(x+\beta)}{1-F(x)}=\frac{R(x+\beta)}{R(x)} \cdot \frac{1-G(x+\beta)}{1-G(x)} .
$$

Thus, by (3.1) there exist $x_{0} \varepsilon \mathbf{R}$ such that

$$
[1-F(x+\beta)] /[1-F(x)] \geq \alpha / 2 \text { for all finite } x \geq x_{0}
$$

Furthermore

$$
\frac{1-F(x+\beta)}{1-F(x)} \geq 1-F(x+\beta) \geq 1-F\left(x_{0}+\beta\right)>0
$$

for all $x<x_{0}$.

Let $\alpha^{\prime}=\min \left\{\alpha / 2,1-F\left(x_{0}+\beta\right)\right\}>0$, then it holds that

$$
[1-F(x+\beta)] /[1-F(x)] \geq \alpha^{\prime} \quad \text { for all finite } x
$$

Therefore, by Theorem 1.3 (c), it holds that $F \varepsilon\{A O P\}$.
Similarly, we can prove the converse.
(d) The proof is analogous to that of part (c). Q.E.D.

COROLLARY 3.1. Suppose $F$ and $G$ are distribution functions as in Theorem 3.1, then $F$ and $G$ belong to the same class defined in Proposition 3.2 .

REMARK 3.1. Let $F$ and $G$ be distribution functions such that $[1-F(x)] /[1-G(x)] \rightarrow c \quad$ as $x \rightarrow \infty$, where $0<c<\infty$. Then $F$ and $G$ belong to the same class.

Now let us consider the heaviness of the tails of distributions, then we have the following theorem.

THEOREM 3.2. Let $F$ and $G$ be distribution functions.
(a) If $F \in\{\mathrm{AOR}\}$ and $G \in\{\mathrm{AOP}\}$, then $\lim _{x \rightarrow \infty}[1-F(x)] /[1-G(x)]=0$.
(b) If $F \in\{\operatorname{ROR}\}$ and $G \varepsilon\{\operatorname{ROP}\}$, then $\lim _{x \rightarrow \infty}[1-F(x)] /[1-G(x)]=0$.
(c) If $F \in\{\mathrm{AOR}\}$ and $G \in\{\operatorname{ROP}\}$, then $\lim _{x \rightarrow \infty}[1-F(x)] /[1-G(x)]=0$.

PROOF. (a) Suppose $F \in\{A O R\}$ and $G \varepsilon\{A O P\}$, then by Theorem 1.3 (a) and (c), it holds that

$$
\lim _{x \rightarrow \infty}[1-F(x+\varepsilon)] /[1-F(x)]=0 \quad \text { for all } \varepsilon>0
$$

and there exist $\alpha>0$ and $\beta>0$ such that

$$
[1-G(x+\beta)] /[1-G(x)] \geq \alpha \quad \text { for all finite } x
$$

Thus there exists $x_{0} \varepsilon \mathbf{R}$ such that

$$
[1-F(x+\beta)] /[1-F(x)] \leq \alpha / 2 \quad \text { for all } x \geq x_{0}
$$

For sufficiently large $x$, there exists an $n \varepsilon \mathbf{N}$ such that

$$
x_{0}+n B \leq x<x_{0}+(n+1) \beta
$$

Hence we have

$$
\begin{aligned}
\frac{1-F(x)}{1-G(x)} & \leq \frac{1-F\left(x_{0}+n \beta\right)}{1-G\left(x_{0}+(n+1) \beta\right)} \leq \frac{(\alpha / 2)^{n}\left(1-F\left(x_{0}\right)\right)}{\alpha^{n+1}\left(1-G\left(x_{0}\right)\right)} \\
& =(1 / 2)^{n} \frac{1-F\left(x_{0}\right)}{\alpha\left(1-G\left(x_{0}\right)\right)}+0 \quad \text { as } x \rightarrow \infty
\end{aligned}
$$

because $n \rightarrow \infty$ as $x+\infty$.
(b) The proof is analogous to that of part (a).
(c) Using the relation $\{A O R\} \subset\{R O R\}$ (see Proposition 3.1 (a)), the proof is trivial from (b). Q.E.D.

REMARK 3.2. This theorem shows a connection between heaviness of tails and outlier properties.

### 3.4. RELATIONS BETwEEN the OUTLIER PROPERTIES aND the types of extreme VALUE DISTRIBUTIONS

In this section we show some relations between the outlier properties and the types of extreme value distributions.

THEOREM 4.1. If $F \in \mathbf{D}\left(\Phi_{\alpha}\right)$, then $F \varepsilon\{R O P\}$, i.e., $F$ belongs to the class V.

PROOF. Suppose $F \in \mathbf{D}\left(\Phi_{\alpha}\right)$, then $1-F(x)$ is $-\alpha$-varying at infinity (see Theorem 1.1 in Section 1.1). Thus, for any $k>1$

$$
\lim _{x \rightarrow \infty}[1-F(k x)] /[1-F(x)]=k^{-\alpha}>0
$$

Hence there exists $x_{0} \in \mathbf{R}$ such that

$$
[1-F(k x)] /[1-F(x)]>k^{-\alpha} / 2>0 \quad \text { for all finite } x \geq x_{0}
$$

Moreover

$$
\begin{aligned}
& {[1-F(k x)] /[1-F(x)] \geq 1-F(k x) } \\
& \geq 1-F\left(k x_{0}\right)>0 \quad \text { for all } x<x_{0}
\end{aligned}
$$

Thus, let $\delta=\min \left\{k^{-\alpha} / 2,1-F\left(k x_{0}\right)\right\}>0$, then

$$
[1-F(k x)] /[1-F(x)] \geq \delta \quad \text { for all finite } x
$$

Hence, by Theorem $1.3(d)$, we have $F \in\{R O P\}$. Q.E.D.

EXAMPLE 4.1. For $\alpha>0$ and $c>0$, let $F$ be a distribution function such that $1-F(x) \sim c x^{-\alpha}$ for $x>1$. Then, by Theorem 4.1 we have $F \in\{R O P\}$.

THEOREM 4.2. If $F \in \mathbf{D}(\Lambda)$, then $F \in\{R O R\}$.

PROOF. Suppose $F \in \mathbf{D}(\Lambda)$, then it is well-known that $F$ is relative stable (Gnedenko [8]), i.e., $F$ satisfies the condition (b) in Theorem 1.3. Thus we have the conclusion. Q.E.D.

EXAMPLE 4.2. For $a>0, c>0, \alpha>0$ and $b \in R$, let $f$ be a density such that $f(x) \sim a x^{b} e^{-c x^{\alpha}}$ and the corresponding distribution function is $F$. Then by Theorem 3.8 in Section 1.3 , it holds that $F \varepsilon D(\Lambda)$. Thus we have $F \in\{\operatorname{ROR}\}$.

By Theorem 1.4 it is easy to see that $F$ belongs to the class I if $\alpha>1$, and to the class III if $\alpha \leq 1$.

## CHAPTER 4

## ORDER STATISTICS IN SEQUENTIAL LIFE TESTING AND NON-REGULAR ESTIMATION

### 4.1. Introduction

In this chapter we deal with the applications of the order statistics in life testing problem and non-regular estimation problem.

Padgett and wei [18] considered the following life testing problem where the test is terminated by time $t_{0}$. Let $n$ independent items be put on test at the outset, and when an item fails, it is not replaced. Suppose that the distribution function of the life time of each item is $F_{\theta}(t)$ and the corresponding density is $f_{\theta}(t)$. Also, it is assumed that $F_{\theta}(t)$ is stochastically nondecreasing in $\theta$, i.e., $F_{\theta_{1}}(t) \geq F_{\theta_{2}}(t)$, if $\theta_{1}<\theta_{2}, t \geq 0$. The hypotheses which were considered are

$$
\begin{equation*}
H_{0}: \theta \geq \theta_{0} \text { versus } H_{1}: \theta \leq \theta_{1} \tag{1.1}
\end{equation*}
$$

where $\theta_{1}<\theta_{0}$.
Padgett and Wei [18] proposed and analyzed a one-sided sequential procedure for testing (1.1) based on the random function $X_{n}(t)$, which represents the number of failures among the $n$ items before or at time $t \leq t_{0}$. They explained several advantages of using $X_{n}(t)$ as the test statistic. Their procedure allows a quick rejection of $H_{0}$ when $H_{1}$ is true.

In Section 4.2 we improve Lemma 1 and Theorem 1 of Padgett and Wei [18], and derive the average sampling time. In Section 4.3 we propose and analyze a sequential procedure which allows a quick acceptance of $H_{0}$ when $H_{0}$ is true. In Appendix we prove the lemmas in Section 4.3.

Weiss and Wolfowitz [31] developed the following estimation theory. For each positive integer $n$ let $\mathbf{X}(n)$ denote the (finite) vector of random variables of which the estimator is to be a function. ( $\mathbf{X}(n)$ need not have $n$ components, nor need its components be independently or identically distributed.) Let $K_{n}(\mathbf{x} \mid \theta)$ be the density of $\mathbf{X}(n)$ at the point $\mathbf{x}$ with respect to a o-finite measure $\mu_{n}$ when $\theta$ is the value of the parameter. The latter is a point of the known open set $\theta$. An estimator (of $\theta$ ) is a Borel measurable function of $\mathbf{X}(n)$ with values in $\theta$. We assume, for the sake of simplicity, that $\theta$ is a subset of the real line.

For each $n$ let $k(n)$ be a normalizing factor for the family $K_{n}(\cdot \mid \cdot)$. Let $R$ be a bounded, Borel measurable subset of the real line. A maximum probability estimator (m.p.e.) with respect to $R$ is one which maximizes, with respect to $d$,

$$
\int K_{n}(\mathbf{X}(n) \mid \theta) d \theta
$$

the integral being over the set $\{d-R / k(n)\}$. (For simplicity we assume that there is a unique maximum.)

Let $h>0$ be any number. We shall say that a sequence $\left\{\theta_{n}\right\}$ is in $H(h)$ (for a special point which below will always be $\theta_{0}$ ), if $\left|k(n)\left(\theta_{n}-\theta_{0}\right)\right| \leq h$ for $n=1,2, \ldots$.

Weiss and Wolfowitz [31] proved the following theorem.

THEOREM 1.1. Let $M_{n}$ be an m.p.e. with respect to $R$ such that: For any $h>0$ and any sequence $\left\{\theta_{n}\right\}$ in $H(h)$ we have

$$
\lim _{n \rightarrow \infty} P_{\theta_{n}}\left\{k(n)\left(M_{n}-\theta_{n}\right) \varepsilon R\right\}=\alpha\left(\theta_{0}\right), \text { say }
$$

Let $\varepsilon$ and $\delta$ be arbitrary but positive. For $h$ sufficiently large we have, for any sequence $\left\{\theta_{n}\right\}$ in $H(h)$,

$$
\frac{\lim _{n \rightarrow \infty}}{} P_{\theta_{n}}\left\{\left|k(n)\left(M_{n}-\theta_{n}\right)\right|<\delta h\right\} \geq 1-\varepsilon .
$$

Let $T_{n}$ be any (competing) estimator such that for any $h>0$ and any sequence $\left\{\theta_{n}\right\}$ in $H(h)$ we have

$$
\lim _{n \rightarrow \infty}\left[P_{\theta_{n}}\left\{k(n)\left(T_{n}-\theta_{n}\right) \in R\right\}-P_{\theta_{0}}\left\{k(n)\left(T_{n}-\theta_{0}\right) \varepsilon R\right\}\right]=0 .
$$

Then

$$
\overline{\lim }_{n \rightarrow \infty} P_{\theta_{0}}\left\{k(n)\left(T_{n}-\theta_{0}\right) \varepsilon R\right\} \leq \alpha\left(\theta_{0}\right) .
$$

Weiss and Wolfowitz [31] also showed that a function of extreme order statistic is a m.p.e. in some non-regular case where distributions are concentrated on finite intervals.

In Section 4.4 in order to compare two sequences of m.p.e.'s more precisely, we introduce a notion of the second order efficiency which we apply to some non-regular estimation problems.

### 4.2. A sequential test in time truncated life testing, I

To test the hypotheses (1.1) Padgett and Wei [18] defined the following stopping rule: Let $T=\inf \left\{t \geq 0: X_{n}(t) \geq a t+b\right\}$ and given $t_{0}$, stop testing at time min $\left(t_{0}, T\right)$ and reject $H_{0}$ if and only if $T \leq t_{0}$. We consider the same stopping rule. The following lemma is an extension of Lemma 1 of Padgett and Wei [18].

LEMMA 2.1. Let $n$ items be put on test at the outset. Also, let the distribution function of the life times of these $n$ items be $F(t)$ and the corresponding density be $f(t)$. Then the probability that the path $X_{n}(t)$ lies entirely below the line $y=a t+b(a>0, b \geq 0)$ for $a l l t \leq u$, say $P\left(X_{n}(t)<a t+b\right.$, for $\left.a l l t \leq u\right)$, is

$$
\sum_{\eta=0}^{n}(\imath!)\binom{n}{\eta} h^{n} \phi_{Z}(u) \cdot(\bar{F}(u))^{n-\eta}
$$

where $\bar{F}(u)=1-F(u), \quad{ }_{h} \phi_{0}(u)=1, h=-b / a$, for $u>\tau_{\tau}+h$

$$
\begin{aligned}
& h^{\phi}(u)=\sum_{i=1}^{i+1} h^{C} C_{i+1}^{i} \cdot h_{i}^{\rho_{i}+1}(u) \text {, and } 0 \text { otherwise, } \\
& h^{\rho_{k}^{j}}(\cdot)=(F(\cdot)-F(k \tau+h))^{j-k} /(j-k)!, \quad 1 \leq k \leq j, \quad \tau=1 / a, \\
& h_{r}^{C_{r}^{j}}=h_{r}^{C_{r}^{j-1}}, 1 \leq r \leq j-1, \\
& h^{C_{j}^{j}}=-\sum_{i=1}^{j-2} \hbar^{c}{ }_{i}^{j} h^{\rho_{i}^{j}}((j-1) \tau+h), j \leq Z+1, \\
& { }_{h} C_{1}^{1}=1 \text {, and the empty summation is zero. }
\end{aligned}
$$

REMARK 2.1. If $b=0$ then we have the same result of Lemma 1 of Padgett and Wei [18]. This lemma is more useful to prove Theorems 2.1 and 2.2 than Lemma 1 of [18] is.

REMARK 2.2. The proof is the same as that of Lemma 1 of Padgett and Wei [18] with $j \tau$ replaced by $j \tau+h$, so we omit it.

Using this result, we have the following theorem for the distribution of $T$.

THEOREM 2.1.

$$
\begin{aligned}
H_{\theta}(s) & =P_{\theta}(T \leq s)=1-P_{\theta}(T>s) \\
& =1-P_{\theta}\left(X_{n}(t)<a t+b, \text { for } a l l t \leq s\right) \\
& =1-\sum_{l=0}^{n}\binom{n}{l} \cdot(l!)_{h} \phi_{\eta}(s)\left(\bar{F}_{\theta}(s)\right)^{n-l}
\end{aligned}
$$

for $0 \leq s$, where

$$
\bar{F}_{\theta}(\cdot)=1-F_{\theta}(\cdot),
$$

$h^{\phi}(s)$ is defined as $h^{\phi} \eta_{Z}$ in Lemma 2.1 except $F(\cdot)$ is replaced by $F_{\theta}(\cdot)$.

REMARK 2.3. This expression for $H_{\theta}$ is simpler than that of Theorem 1 of Padgett and Wei [18]. Although both expressions are identical, it is difficult to derive directly the one from the other by simple manipulation.

As in Padgett and Wei [18], the derivative $h_{\theta}(s)$ of $H_{\theta}(s)$ at $s\left(\leq t_{0}\right)$ exists except for those points $t$ such that $a t+b$ is integer. However the probability of having failures exactly at those points is zero. Therefore, we represent the average sampling time of the test procedure as

$$
\int_{0}^{t_{0}} \operatorname{sh}(s) d s+t_{0} P_{\theta}\left(T>t_{0}\right)=\int_{0}^{t_{0}} s H_{\theta}\{d s\}+t_{0}\left[1-H_{\theta}\left(t_{0}\right)\right]
$$

Then we have the following theorem.

THEOREM 2.2. The average sampling time of the test procedure is given by

$$
\begin{aligned}
\int_{0}^{t_{0}} s H_{\theta}\{d s\} & +t_{0} P_{\theta}\left(T>t_{0}\right)=\int_{0}^{t_{0}}\left[1-H_{\theta}(s)\right] d s \\
& =\sum_{l=0}^{n}(\tau!)\binom{n}{l} \int_{0}^{t_{0}} h^{\phi_{\imath}}(s)\left(\bar{F}_{\theta}(s)\right)^{n-l} d s .
\end{aligned}
$$

PROOF. It is well-known that

$$
\int_{0}^{t_{0}+} s H_{\theta}\{d s\}=-t_{0}\left[1-H_{\theta}\left(t_{0}\right)\right]+\int_{0}^{t_{0}}\left[1-H_{\theta}(s)\right] d s
$$

(see for example Feller [4] (p.150)). Then, by using Theorem 2.1 we can obtain the result. Q.E.D.

### 4.3. A sequential test in time truncated life testing, II

To test the hypotheses (1.1) we define the following stopping rule: For $t_{0}>0$, let $T^{*}=\inf \left\{t: X_{n}(t) \geq n^{*}\right.$ or $\left.X_{n}(t) \leq a t+b\right\}$, where $a>0, b<0$, $n^{*}$ is a positive integer $(<n)$ and $a t_{0}+b=n^{*}-1$. Stop testing at time $\min \left(t_{0}, T^{*}\right)$, and reject $H_{0}$ if and only if $X_{n}(t)=n^{*}$. Following lemmas are needed to derive the distribution of $T^{*}$. Proofs of those lemmas are shown in Appendix.

LEMMA 3.1. Let the distribution function of the life time be $F(t)$ and the corresponding density be $f(t)$. We put for $i=1,2, \cdots, n$,

$$
\Phi_{i}=\int_{0}^{h} \int_{t_{1}}^{\tau+h} \cdots \int_{t_{i-2}}^{(i-2) \tau+h} \prod_{i-1}^{(i-1) \tau+h} i{ }_{k=1}^{i} f\left(t_{k}\right) d t_{1} \cdots d i_{i}
$$

Where $\tau>0$ and $h>0$. Then we have

$$
\phi_{i}=\sum_{k=0}^{i} C_{k}^{i} \rho_{k}^{i}(0)
$$

where

$$
\begin{aligned}
& \rho_{k}^{j}(\cdot)=\frac{\left\{F((i-1-k) \tau+h)-F(\cdot)^{j-k}\right.}{(j-k)!}, \quad 0 \leq k \leq j \leq i, \\
& \rho_{k}^{k}(\cdot)=1, \\
& C_{k}^{j}=C_{k}^{j-1}, \quad 0 \leq k \leq j-1, \\
& C_{j}^{j}=-\sum_{k=0}^{j-2} C_{k}^{j} \rho_{k}^{j}((i-j) \tau+h), \\
& C_{0}^{0}=1,
\end{aligned}
$$

and the empty summation is zero.

LEMMA 3.2. Let $n$ independent items be put on test at the outset. Also let the distribution function of the life times of these $n$ items be $F_{\theta}(t)$ and the corresponding density be $f_{\theta}(t)$. Then it holds that

$$
\begin{aligned}
& P_{\theta}\left(X_{n}(t)>a t+b, \text { for } a l l t \leq u\right) \\
= & 1-\sum_{i=0}^{[a u+b]}\left(1-F_{\theta}(i \tau+h)\right)^{n-i}{ }_{n} P_{i} \cdot \phi_{i} \quad \text { for } u \text { such that }[a u+b] \leq n,
\end{aligned}
$$

where $a>0, b<0, h=-b / a, \tau=1 / a,{ }_{n} P_{0}=1, \phi_{0}=1$,

$$
{ }_{n} P_{k}=n(n-1) \cdots(n-k+1), k=1,2, \cdots, n,
$$

$\phi_{i}$ is defined as $\phi_{i}$ in Lemma 3.1 except that $F$ and $f$ are replaced by $F_{\theta}$ and $f_{\theta}$, respectively, [•] is the greatest integer function, and the empty summation is zero.

LEMMA 3.3. Under the same assumptions of Lemma 3.2, for $u \leq t_{0}$, we have

$$
\begin{aligned}
& P_{\theta}\left(a t+b<X_{n}(t)<n^{*}, \text { for all } t \leq u\right) \\
= & \sum_{j=l}^{n^{*}\binom{n}{j}\left(\bar{F}_{\theta}(u)\right)^{n-j}\left\{F_{\theta}(u)^{j}-\sum_{i=0}^{\imath-1}\left(F_{\theta}(u)-F_{\theta}(i \tau+h)\right)^{j-i} \cdot{ }_{j} P_{i} \cdot \phi_{i}\right\},}
\end{aligned}
$$

where $l=[a u+b]+1$ and $\bar{F}_{\theta}(\cdot)=1-F_{\theta}(\cdot)$.
By using these lemmas, we have the following theorems.

## THEOREM 3.1.

$$
\begin{aligned}
& H_{\theta}^{*}(s)=P_{\theta}\left(T^{*} \leq s\right)=1-P_{\theta}\left(T^{*}>s\right) \\
&\left.=1-\sum_{j=[a s+b]+1}^{n^{*}} \begin{array}{l}
\text { ( } \\
j \\
j
\end{array}\right)\left(\bar{F}_{\theta}(s)\right)^{n-j} \\
& \times\left\{F_{\theta}(s)^{j}-\sum_{i=0}^{[a s+b]}\left(F_{\theta}(s)-F_{\theta}(i \tau+h)\right)^{j-i} \cdot{ }_{j} P_{i} \cdot \phi_{i}\right\} \text { for } s<t_{0}
\end{aligned}
$$

and $H_{\theta}^{*}(s)=1$ for $s \geq t_{0}$.
PROOF. It is trivial from Lemma 3.3.

THEOREM 3.2. The O.C. function, $L^{*}(\theta)$, of this sequential procedure is

$$
\begin{aligned}
L^{*}(\theta) & =1-P_{\theta}\left(X_{n}(t)>a t+b, \text { for all } t \leq t_{0}\right) \\
& =\sum_{i=0}^{n *-1}\left(1-F_{\theta}(i \tau+h)\right) \cdot{ }^{n-i}{ }^{P} i_{i} \cdot \phi_{i} .
\end{aligned}
$$

PROOF. By using Lemma 3.2 it is easy to show.

Note that the derivative $h_{\theta}^{*}(s)$ of $H_{\theta}^{*}(s)$ at $s\left(\leq t_{0}\right)$ exists except for those points $t$ such that $a t+b$ is an integer. However the probability of having failures exactly at those points is zero. Therefore the average sampling time of the test procedure is given by

$$
\int_{0}^{t_{0}} s h_{\theta}^{*}(s) d s+t_{0} P_{\theta}\left(T^{*}>t_{0}\right)=\int_{0}^{t_{0}}\left\{1-H_{\theta}^{*}(s)\right\} d s .
$$

See Section 4.2.
Then we have the following theorem.

THEOREM 3.3. The average sampling time of the test procedure is

$$
\begin{gathered}
\int_{0}^{t_{0}}\left\{1-H_{\theta}^{*}(s)\right\} d s \\
\left.=\int_{0}^{t_{0}} \sum_{j=[a s+b]+1}^{n^{*-1}} \begin{array}{c}
n \\
j
\end{array}\right)\left(\bar{F}_{\theta}(s)\right)^{n-j}\left\{F_{\theta}(s)^{j}-\sum_{i=0}^{[a s+b]}\left(F_{\theta}(s)\right.\right. \\
\left.\left.\quad-F_{\theta}(i \tau+h)\right)^{j-i} \cdot{ }_{j} P_{i} \cdot \phi_{i}\right\} d s .
\end{gathered}
$$

PROOF. By using Theorem 3.1 we can obtain the result.

### 4.4. Non-regular estimation problem

If $\left\{Z_{n}^{(1)}\right\}$ and $\left\{Z_{n}^{(2)}\right\}$ are two sequences of m.p.e.'s, then the asymptotic risks of them are equivalent. To evaluate the relative performance of them for finite observations, we define second order efficiency.

DEFINITION 4.1. Suppose, $\left\{Z^{(1)} \begin{array}{c}n\end{array}\right\}$ and $\left\{Z_{n}^{(2)}\right\}$ are sequences of m.p.e.'s (of $\theta \varepsilon \theta$, a parameter space) with risks $\left\{\beta_{n}^{(1)}(\theta)\right\}$ and $\left\{\beta_{n}^{(2)}(\theta)\right\}$, respectively. If there exists

$$
\begin{aligned}
S E(1,2 ; \theta) & =\lim _{n \rightarrow \infty} S E_{n}(1,2 ; \theta)=\lim _{n \rightarrow \infty}\left|\frac{\beta^{(2)}(\theta)}{\frac{n}{n}(\theta)}\right|^{n} \\
& \geq 1 \text { for all } \theta \varepsilon \theta,
\end{aligned}
$$

and there exists at least one $\theta^{\prime} \varepsilon \theta$, such that

$$
S E\left(1,2 ; \theta^{\prime}\right)>1
$$

then we say $\left\{Z^{(1)}\right\}$ is more efficient than $\left\{Z_{n}^{(2)}\right\}$ in the sense of second order.

REMARK 4.1. If $S E(1,2 ; \theta)>1$, then $\beta_{n}^{(1)}(\theta)<\beta_{n}^{(2)}(\theta)$ for sufficiently large $n$.

Now we consider a non-regular estimation problem as follows.
Suppose $X_{1}, X_{2}, \cdots, X_{n}$ are independent real-valued random variables with a common distribution function $F(x \mid \theta)$ whose density is $f(x \mid \theta)$, where $\theta$ is a real parameter. Suppose also that for any $\theta, \theta<A(\theta)$ (a known function of $\theta), A^{\prime}(\theta)=d A(\theta) / d \theta$ is positive,

$$
\begin{aligned}
& f(x \mid \theta)=0, \quad x<\theta \quad \text { or } \quad x>A(\theta) \\
& f(\theta \mid \theta)=g(\theta)>0, \quad f(A(\theta) \mid \theta)=h(\theta)>0
\end{aligned}
$$

and there exist $g_{+}^{\prime}(\theta)=f_{+}^{\prime}(\theta \mid \theta), h_{-}^{\prime}(\theta)=f_{-}^{\prime}(A(\theta) \mid \theta)$ and $A^{\prime \prime}(\theta)$. For detail
see Weiss and Wolfowitz [31] (pp. 46-48). In this case, by Corollary 2.2 in Section $1.2 n\left(\min X_{i}-\theta\right)$ and $n\left(\theta-A^{-1}\left(\max X_{i}\right)\right)$ are asymptotically exponentially distributed.

THEOREM 4.1. Suppose $r$ is a positive constant and $C(\theta)=g(\theta)-h(\theta) A^{\prime}(\theta)$ $=0$. Then $Z_{n}^{(1)}=\min X_{i}-r / n$ and $Z_{n}^{(2)}=A^{-1}\left(\max X_{i}\right)+r / n$ are m.p.e.'s with respect to $R$ defined by

$$
\begin{equation*}
R=(-r, r) \tag{4.1}
\end{equation*}
$$

(see Weiss and Wolfowitz [31] (p.48)), and we have

$$
\begin{equation*}
S E(1,2 ; \theta)=\exp \left\{2 r^{2}\left[g_{+}^{\prime}(\theta)+h_{-}^{\prime}(\theta) A^{\prime 2}(\theta)+h(\theta) A^{\prime \prime}(\theta)\right]\right\} \tag{4.2}
\end{equation*}
$$

PROOF. From Taylor expansion, we have

$$
\int_{\theta}^{t} f(x \mid \theta) d x=g(\theta)(t-\theta)+\frac{1}{2} g_{+}^{\prime}(\theta)(t-\theta)^{2}+o(1)(t-\theta)^{2}
$$

as $t \rightarrow \theta+0$. By

$$
\beta_{n}^{(i)}(\theta)=P_{\theta}\left\{n\left(2^{(i)} n-\theta\right) \notin(-r, r)\right\}, \quad i=1,2,
$$

we have

$$
\begin{aligned}
{ }_{B}^{(1)}(\theta) & =P_{\theta}\left\{n\left(\min X_{i}-r / n-\theta\right) \notin(-r, r)\right\} \\
& =P_{\theta}\{\min X-\theta \geq 2 r / n\} \\
& =P_{\theta}^{n}\{X-\theta \geq 2 r / n\} \\
& =\left[1-P_{\theta}\{X-\theta<2 r / n\}\right]^{n} \\
& =\left[1-2 r g(\theta) / n-\left\{2 r^{2} g_{+}^{\prime}(\theta)+o(1)\right\} / n^{2}\right]^{n} \\
& =\{1-2 r g(\theta) / n\}^{n}\left|1-\frac{2 r^{2} g_{+}^{\prime}(\theta)+o(1)}{n^{2}(1-2 r g(\theta) / n)}\right|^{n}
\end{aligned}
$$

Similarly, we have

$$
B_{n}^{(2)}(\theta)=\left\{1-\frac{2 r h(\theta) A^{\prime}(\theta)}{n}\right\}^{n}\left\{1+\frac{2 r^{2}\left[h_{-}^{\prime}(\theta) A^{\prime 2}(\theta)+h(\theta) A^{\prime \prime}(\theta)\right.}{n^{2}\left(1-2 r h(\theta) A^{\prime}(\theta) / n\right)}\right\}^{n}
$$

Taking the ratio of the last two expressions and noting that $C(\theta)=0$, we obtain (4.2). Q.E.D.

COROLLARY 4.2. Consider a simple case,

$$
\begin{array}{rlrl}
f(x \mid \theta) & =f(x-\theta), & \\
& >0 & & \\
& =0 \quad \text { if } a \leq x \leq b \\
& & & \text { if } x<a \text { or } x>b,
\end{array}
$$

where $a$ and $b$ are known constants and we assume that there exist $f_{+}^{\prime}(a)$ and $f_{-}^{\prime}(b)$. Suppose $f(a)=f(b)=c>0$, then $Z_{n}^{(1)}=\min X_{i}-a-r / n$ and $Z_{n}^{(2)}=\max X_{i}-b+r / n$ are m.p.e.'s with respect to $R$ defined in (4.1), and we have

$$
S E(1,2 ; \theta)=\exp \left\{2 r^{2}\left(f_{+}^{\prime}(a)+f_{-}^{\prime}(b)\right)\right\}
$$

independently of $\theta$.

## Appendix

Proof of Lemma 3.1. For fixed $i$, define

$$
\phi_{i}^{j}\left(t_{i-j}\right)=\int_{t_{i-j}}^{(i-j) \tau+h} \int_{t_{i-1}}^{(i-1) \tau+h} \prod_{k=i-j+1}^{i} f\left(t_{k}\right) d t_{i-j+1} \cdots d t_{i},
$$

where $t_{0}=0$. Then we have

$$
\begin{equation*}
\phi_{i}^{j}\left(t_{i-j}\right)=\sum_{k=0}^{j} C_{k}^{j} \rho_{k}^{j}\left(t_{i-j}\right) \tag{A.1}
\end{equation*}
$$

The result of Lemma 3.1 is the special case of (A.1), i.e.,

$$
\phi_{i}=\phi_{i}^{i}(0)=\sum_{k=0}^{i} C_{k}^{i} \rho_{k}^{i}(0)
$$

The proof of (A.1) is same as that of Lemma 1 of Padgett and Wei [18] and is omitted. Q.E.D.

Proof of Lemma 3.2. Let $T_{1}<T_{2}<\cdots<T_{n}$ be the failure times. Define

$$
\begin{aligned}
Q(u) & =P_{\theta}\left(X_{n}(t)>a t+b, \text { for all } t \leq u\right) \\
& =P_{\theta}\left(T_{i}<\tau(i-1)+h, i=1,2, \cdots, \eta\right)=R_{\eta}
\end{aligned}
$$

where $I=[a u+b]+1$. Then we have

$$
\begin{aligned}
& \left.R_{\imath}=\int_{0}^{h} \int_{t_{1}}^{\tau+h} \cdots \int_{t_{\eta-1}}^{(\eta-1) \tau+h}{ }^{P_{\imath}\left(1-F_{\theta}\right.}\left(t_{\imath}\right)\right) \prod_{i=1}^{n-\eta} \prod_{\theta}\left(t_{i}\right) d t_{1} \cdots d t_{\imath} \\
& =R_{\text {Z-1 }}-\left(1-F_{\theta}((\eta-1) \tau+h)^{n-(\eta-1)} \cdot n^{P} P_{-1} \cdot \phi_{\eta-1} .\right.
\end{aligned}
$$

Therefore

$$
R_{\imath}=Q(u)=1-\sum_{i=0}^{i-1}\left(1-F_{\theta}(i \tau+h)\right)^{n-i} \cdot n_{i} P_{i} \phi_{i}
$$

Q.E.D.

Proof of Lemma 3.3. Suppose that there are exactly $j(\geq Z=[a u+b]+1)$ failures before or at time $u$. Let $T_{1}<T_{2}<\cdots<T_{j}$ be the failure times, where $l \leq j \leq n^{*}-1$. Then, the conditional joint density of $\left(T_{1}, T_{2}, \ldots, T_{j}\right)$ is $j!\Pi_{i=1}^{j} f_{\theta}\left(t_{i}\right) /\left(F_{\theta}(u)\right)^{j}$. For fixed $j$,

$$
a t+b<X_{n}(t)<n^{*}, \text { for all } t \leq u
$$

if and only if

$$
T_{i}<\tau(i-1)+h, i=1, \cdots, \eta, \quad T_{\eta+1}<\cdots<T_{j}<u
$$

and the probability of this event is

$$
\begin{aligned}
\tilde{\phi}_{j}(u) & =\frac{j!}{F_{\theta}(u)^{j}} \int_{0}^{h} \int_{t_{1}}^{\tau+h} \cdot \int_{t_{\eta-1}}^{(\eta-1) \tau+h} \int_{t} \cdots \int_{t}^{j-1} \\
& =\frac{j_{i=1}^{P} f_{\theta}}{F_{\theta}(u)^{j}} \int_{0}^{h} \int_{t_{1}}^{\tau} \cdots t_{t_{\eta-1}}^{\tau+h}\left(F_{\theta}(u)-F_{\theta}\left(t_{\eta}\right)\right)_{1}^{j-\imath} \cdot \prod_{i=1}^{(\eta-1) \tau+h} f_{\theta}\left(t_{i}\right) d t_{1} \cdots d t_{j} \cdot
\end{aligned}
$$

Define $S_{\mathcal{l}}=F_{\theta}(u)^{j} \tilde{\phi}_{j}(u)$. Then we have

$$
S_{\eta}=S_{\eta-1}-\left(F_{\theta}(u)-F_{\theta}((\eta-1) \tau+h)\right)^{j-(\eta-1)} \cdot{ }_{j} P_{\imath-1} \phi_{\eta-1},
$$

so

$$
S_{\imath}=F_{\theta}(u)^{j}-\sum_{i=0}^{\mathcal{1}}\left(F_{\theta}(u)-F_{\theta}(i \tau+h)\right)_{j}^{j-i} P_{i} \cdot \phi_{i}
$$

Therefore, the probability of $a t+b<X_{n}(t)<n^{*}$, for all $t \leq u$ is give by

$$
\begin{aligned}
& \sum_{j=2}^{n^{*}-1}\binom{n}{j} P_{\theta}\left(T_{i}<\tau(i-1)+h, i=1, \cdots, \imath, T_{\eta+1}<\cdots<T_{j}<u\right. \\
& \text { |exactly } j \text { failures before or at time } u \text { ) } \\
& \times P_{\theta} \text { (exactly } j \text { failures before or at time } u \text { ) } \\
& =\sum_{j=l}^{n^{*-1}}\binom{n}{j}\left(F_{\theta}(u)\right)^{n-j}\left\{F_{\theta}(u)^{j}-\sum_{i=0}^{l-1}\left(F_{\theta}(u)-F_{\theta}(i \tau+h)^{j-i}\right) \cdot{ }_{j} P_{i} \cdot \phi_{i}\right\} .
\end{aligned}
$$

## Q.E.D.

## ACKNOWLEDGEMENT

I wish to express my gratitude to Professor M. Okamoto, Osaka University, for his continuous guidance, valuable comments and encouragement. I am greatful to Professor N. Inagaki, Osaka University, for his useful suggestions and encouragement. I wish to thank members of Statistical Seminar Group in Osaka University, Dr. S. Shirahata and Dr. T. Isogai, Osaka University, and Dr. M. Yamaguchi, Fukui University, for their advice and encouragement. I also wish to thank members of Kansai Applied Statistical Research Group, Professor T. Nagai and Dr. M. Goto for their encouragement. Finally, I would like to thank Professor J. Galambos, Temple University, for suggesting the problem dealt with in Section 2.3.
