Use of Thermodynamic Data to Determine Surface Tension and Viscosity of Metallic Alloys
Toshihiro Tanaka, Klaus Hack, and Shigeta Hara

Introduction
During the last three decades, various thermodynamic databases have been compiled to be applied mainly to the calculation of phase diagrams of alloys, salts, and oxides. The accumulation and assessment of thermodynamic data and phase-equilibrium information to establish those databases is sometimes called the CALPHAD (calculated phase diagram) approach. In the CALPHAD approach has been recognized as useful in various aspects of materials science and engineering. In addition to the use of thermodynamic databases for the calculation of phase diagrams, it would be very desirable to apply them to the calculation of other physicochemical quantities, such as surface tension. By doing this, not only can the utility of databases be enlarged, but also a deeper understanding of the physical properties in question can be reached.

On the basis of the concepts just mentioned, we have applied those thermodynamic databases to the calculation of the surface tension of liquid alloys and molten ionic mixtures. In these calculations, we have applied Butler’s equation for the surface tension of liquid alloys. In addition, we have modified Butler’s equation to be extended to molten ionic mixtures by considering the relaxation structure in the surface. These approaches will lead us to develop a multifunctional, data-bank system that will be widely applicable in the evaluation of physicochemical properties of liquid alloys and molten ionic mixtures from thermodynamic data.

In this article, we explain some physical models for the surface tension and viscosity of liquid alloys and molten ionic mixtures, in which thermodynamic data can be directly applied to evaluate these physical properties. In addition, the concept for the just-mentioned multifunctional thermodynamic data-bank system will be described by demonstrating the simultaneous calculation of phase diagrams, surface tension, and viscosity of some alloys used for new, Pb-free soldering materials.

Butler’s Equation for Calculating Surface Tension of A-B Binary Liquid Alloys
Several authors have proposed calculations of surface tension of liquid alloys by employing thermodynamic data, as shown in Table 1. Their principles are based on Butler’s equation, which is expressed for surface tension $\gamma$ of any A-B binary liquid alloy as follows:

$$\gamma = \gamma_A + \frac{RT}{A_\gamma} \ln \frac{1-N_B^A}{1-N_B^A}$$

Butler derived Equation 1 assuming an equilibrium between a bulk phase and a surface phase, which is regarded as a hypothetical independent phase. In Equation 1, $R$ is the gas constant, $T$ is the temperature, $\sigma$ is the surface tension of pure liquid $X$, and $A_\gamma$ is the molar surface area in a monolayer of pure liquid $X$ ($X = A$ or $B$). $A_\gamma$ can be obtained from

$$A_\gamma = \ln L_{1/3} V_x$$

where $N_B$ is Avogadro’s number, and $V_x$ is the molar volume of pure liquid $X$. $L$ in Equation 2 is usually set to be 1.091 for liquid metals, assuming close-packed structures. Since no exact information is available for the value of $L$ in Equation 2 for ionic melts, $L = 1$ is used approximately for the fused salts. $N_B^A$ and $N_B^B$ in Equation 1 are mole fractions of a component $X$ in a surface phase and a bulk phase, respectively; $G_{A-B}^X(T, N_B^A)$ is the partial excess Gibbs energy of $X$ in the surface phase as a function of $T$ and $N_B^A$; $G_{A-B}^X(T, N_B^B)$ is the partial excess Gibbs energy of $X$ in the bulk phase as a function of $T$ and $N_B^B$ ($X = A$ or $B$).

Relationship between Excess Gibbs Energy in Bulk and Surface Phases
Since $G_{A-B}^X(T, N_B^A)$ in Equation 1 can be obtained directly from thermodynamic databases, we only need the additional information on $G_{A-B}^X(T, N_B^B)$ in the surface phase. The authors have shown in Table 1 that Butler’s equation is applicable to A-B binary liquid alloys. Butler’s equation is applicable to A-B binary liquid alloys.

$$\gamma = \gamma_A + \frac{RT}{A_\gamma} \ln \frac{1-N_B^A}{1-N_B^A}$$

where $\beta_{A-B}$ is a parameter corresponding to the ratio of the coordination number in the surface phase $Z_s$ to that in the bulk phase $Z_b$. Equation 3 means that $G_{A-B}^X(T, N_B^A)$, which has the same formula as $G_{A-B}^X(T, N_B^B)$, is obtained by replacing $N_B^A$ by $N_B^B$ in $G_{A-B}^X(T, N_B^B)$ ($X = A$ or $B$) and then, multiplying $G_{A-B}^X$ by $G_{A-B}^X(T, N_B^B)$. Speiser et al. proposed Equation 3 with $\beta_{A-B}$ as $Z_s/Z_b = 9/12 = 3/4$ on the basis of the assumption that the excess Gibbs energy in the bulk phase is proportional to the coordination number $Z_b$ ($Z_b = 12$), and that the coordination number...

(2) Data for Calculation of Surface Tension of Liquid Bi-Sn Alloys

$\sigma_{\text{sn}}$ (N m$^{-1}$) = 0.458 – 0.07 x (T – 544), $\sigma_{\text{sn}}$ (N m$^{-1}$) = 0.560 – 0.09 x (T – 505) (19)

$\Gamma$ (m$^2$ mol$^{-1}$) = 20.8 x 10$^{-6}$ x (1 + 1.17 x 10$^{-1}$(T – 544)) (19)

$\Gamma$ (m$^2$ mol$^{-1}$) = 17.0 x 10$^{-5}$ x (1 + 0.87 x 10$^{-1}$ (T – 505)) (19)

$\Gamma$ = 490 + 0.97 T, $\Gamma$ = –30–0.235T

$\sigma_{\text{mix}}$ (N m$^{-1}$) = 0.374, 0.380, 0.387, 0.395, 0.403, 0.413, 0.425, 0.439, 0.458, 0.487, 0.551

(3) Calculated Results of Surface Tension of Liquid Bi-Sn Alloys

$\Gamma_{\text{sn}}$ = 0.00, 0.10, 0.20, 0.30, 0.40, 0.50, 0.60, 0.70, 0.80, 0.90, 1.00

$\eta$ (mPa s) = 1.38, 1.32, 1.38, 1.45, 1.51, 1.53, 1.52, 1.48, 1.42, 1.36, 1.44

Figure 1. Relationship between $\sigma_{\text{X}}$ and $\Delta H_{\text{Evax}}$ for pure liquid metals and (b) pure molten salts.

The value of $\beta_{\text{mix}}$ in Equation 3, however, might be affected by other factors in addition to $Z^2/Z^8$; for example, the relaxation of surface structure. Furthermore, when applying Equations 1 and 3 to ionic mixtures, no information on $Z^2/Z^8$ was available. We therefore have determined $\beta_{\text{mix}}$ as follows:

$$\Gamma_{\text{X}} = \Gamma_{\text{X}}(T, N_\text{X}) = (1 – N_\text{X})Z^2\Omega_{\text{AB}}.$$  (5)

Thus we can obtain the following equation:

$$\Gamma_{\text{X}}(T, N_\text{X}) = \frac{Z^2}{Z} \Gamma_{\text{X}}(T, N_{\text{X}}).$$  (6)

The value of $\beta_{\text{mix}}$ in Equation 3, however, might be affected by other factors in addition to $Z^2/Z^8$; for example, the relaxation of surface structure. Furthermore, when applying Equations 1 and 3 to ionic mixtures, no information on $Z^2/Z^8$ was available. We therefore have determined $\beta_{\text{mix}}$ as follows:

$$\sigma_{\text{X}}A_X = (U_X^0 – \Delta E_X) – U_X^0,$$  (7)

where $U_X^0$ is assumed to be $U_X^0 = (Z^2/Z^8)$. In addition, the binding energy $U_X^0$ is replaced by the heat of evaporation $– \Delta H_{\text{Evax}}$. The energy to form the relaxation structure in the surface $\Delta E_X$ in Equation 7 is assumed to be $\Delta E_X = \lambda(U_X^0 – U_X^0)$. Then, Equation 7 is

$$\sigma_{\text{X}}A_X = [1 – \beta^{\text{pure}}] \Delta H_{\text{Evax}}^X.$$  (8)

where $\beta^{\text{pure}} = [Z^2 + \lambda(Z^2 – Z^8)]/Z^8 = (Z^2)/Z^8$ is the apparent ratio of the coordination number in the surface to that in the bulk for pure substances, considering the relaxation of the surface, and $\lambda$ is a proportionality factor.

The relations between $\sigma_{\text{X}}$ and $\Delta H_{\text{Evax}}$ for pure liquid metals and fused salts are shown in Figure 1. From the linear re-
Use of Thermodynamic Data to Determine Surface Tension and Viscosity of Metallic Alloys

The surface tension $\sigma$ of liquid alloys can be calculated as follows:

1. Set temperature $T$ and composition $N_A$ of an alloy.
2. Insert the values for surface tension $\sigma_X$ and molar volume $V_X$ of pure liquid substances at the chosen temperature in Equations 1 and 2.
3. Determine excess Gibbs energies in the bulk phase at the chosen temperature and composition, and substitute them in Equation 1.
4. Then, the two equations on the right-hand side of Equation 1 become an equation with unknown $N_B$. This equation is solved for $N_B$, and the value of $N_B$ is substituted again into, for example, the first equation of the right-hand side of Equation 1 to calculate the surface tension $\sigma$ of the liquid alloy on the left-hand side of Equation 1.

Evaluating Surface Tension of Liquid Alloys

As an exercise in evaluating the surface tension of liquid alloys, let us calculate the surface tension of liquid Bi-Sn alloys from a set of thermodynamic data. In Table I, which have been assessed to give accordance with the phase diagram for this alloy system. The data of $\sigma_X$, $V_X$, and the excess Gibbs energy $\bar{G}^E(T, N_B)$ are given in Table I. Partial excess Gibbs energies $\bar{G}^E_A(T, N_B)$ and $\bar{G}^E_B(T, N_B)$ of components A and B are obtained from the following relations:

$$\bar{G}^E_A(T, N_B) = G^E(T, N_B) - N_B \frac{\partial G^E(T, N_B)}{\partial N_B}$$

$$\bar{G}^E_B(T, N_B) = G^E(T, N_B) - (1 - N_B) \frac{\partial G^E(T, N_B)}{\partial N_B}$$

The partial excess Gibbs energies in the surface are obtained from Equations 3 and 10. Figure 2 and Table I show the calculated results of the surface tension $\sigma$ on liquid Bi-Sn alloys with the calculated results for the phase diagram and the viscosity of these alloys, which are described later. The calculated results of the surface composition $N_B$ of the liquid Bi-Sn alloy are shown in Table I.

We have also calculated the surface tension of liquid Cu-Pb and Fe-S alloys from Equations 1, 2, and 3 with the various values for $\beta^{\text{mix}}$ shown in Table I and $\beta^{\text{mix}} = 0.83$, based on the assumption in Equation 10. Thermodynamic data for Cu-Pb alloys were taken from the assessment by Hayes et al., and for Fe-S alloys, from Lacaize and Sundman. These data are part of the Scientific Group Thermodynamic Europe (SGTE) database.

Figure 3a shows the calculated results of $\sigma$ in liquid Cu-Pb alloys for which activities of the components indicate large positive deviations from Raoult's law. The relation between $N_B$ and $N_B$ in this alloy is also shown in this figure. Figure 3a shows that the calculated results of $\sigma$ for all of the previously mentioned $\beta^{\text{mix}}$ values agree well with the experimental results and that the difference between the calculated $\sigma$ for $\beta^{\text{mix}} = 1$ and that for $\beta^{\text{mix}} = 1/2$ is smaller than 30 mN m$^{-1}$. On the other hand, from the calculated results of $\sigma$ in liquid Fe-Si alloys in Figure 3b, we found that the curves of $\sigma$ calculated for each $\beta^{\text{mix}}$ value can be distinguished from each other, and that the calculated result with $\beta^{\text{mix}} = 0.83$ agrees well with the experimental data. In this alloy, the activities of the components show large negative deviations from Raoult's law. From these calculations, it is observed that in alloys with negative excess Gibbs energy in the bulk, the surface tension deviates positively from that of the ideal alloy as shown in Figure 3b. On the other hand, in alloys with positive excess Gibbs energy in the bulk, the surface tension has the tendency to show negative deviations from that of the ideal alloy (Figure 3a). We found that this rule can be generally applied to liquid alloys on the basis of Equations 1–3 and 10.

Thermodynamic Evaluation of the Surface Tension of Molten Ionic Mixtures in Common Ion Alkali-Halide Systems

As shown in the preceding sections, the calculated results of $\sigma$ for liquid alloys from Equations 1–3 and the assumption of Equation 10 agree well with the experimental data. As shown in Figure 4, however, the calculated results (chain curves) from these equations for molten ionic mixtures show some discrepancies with the experimental data. As indicated in Figure 3, we found that there exists a general relationship between the composition dependence of the excess Gibbs energy in the bulk and that of the surface tension $\sigma$ in liquid alloys. However, as shown in Figure 4, the experimental results of the surface tension of those molten ionic mixtures, of which excess Gibbs energies are negative, show negative deviations from that of the ideal mixture (dotted curves). The calculated results of the surface tension do not satisfy the experimental results when Equations 1–3 and 10 are used, because the calculated results (chain curves) based on these equations deviate positively from those of the
Use of Thermodynamic Data to Determine Surface Tension and Viscosity of Metallic Alloys

Figure 3. Calculated results of surface tension with experimental values in (a) liquid Cu-Pb and (b) Fe-Si alloys.

Figure 4. Calculated results of surface tension of molten ionic mixtures in common ion alkali-halide systems. (a) is LiCl-KCl, (b) is NaCl-LiCl, (c) is CsBr-LiBr, and (d) is RbBr-LiBr. --- --- ---: Equation 1 + $\beta^{\text{mol}} = 0.94$ in Equation 9; □: experimental results; --- --- ---: ideal alloys in Equation 1; --- --- --- --- ---: Equation 2 + Equation 13 + Equation 14.

ideal mixture (dotted curves). Thus the results in Figures 3 and 4 show that some additional factors have to be considered in Equations 1 and 3 for molten ionic mixtures. We have, therefore, derived new equations for the surface tension of molten ionic mixtures, considering the effect of the surface-relaxation structure on the excess Gibbs energy and the size effect on the mixing entropy as follows:

$$
\sigma = \sigma_A + \frac{RT}{A_A} \ln \frac{D^x_A}{D^x_B} + \frac{1}{A_A} G^{d_A}(T, N^b_0)
$$

and

$$
D^x_A = N^a_A - N^d_A
$$

and

$$
D^x_B = N^a_B - N^d_B
$$

where $d_A$ and $d_B$ are the ionic distances of the substances A and B, which are assumed here to be the sum of the radii of the cation and anion for pure salts A and B. $\xi (-d_A/d_B)$ is the ratio of the ionic distance in the surface phase $d_A$ to that in the bulk phase $d_B$. The change in the ionic distance in the surface is caused by relaxation at the surface. $\xi$ has been evaluated to be 0.97 by Sawada and Nakamura from their theoretical work on the displacement of ions at the surface. $Z^A/Z^B = B^{\text{mix}} = 0.94$ has been obtained in Equation 8. Figure 4 shows the calculated results (solid curves) from Equations 2, 13, and 14 by using thermodynamic data of $G^{d_A}(T, N^b_0)$ stored in the database²³ which permit the calculation of phase diagrams of ionic mixtures. As shown in this figure, the calculated results (solid curves) agree well with the experimental data.²⁴

Evaluating Viscosity of Liquid Alloys and Its Application to Soldering Materials

Some models for evaluating the viscosity of liquid alloys have been proposed, in which thermodynamic data can be applied directly. Two models are represented in this section.

Hirai²⁵ has presented an equation for the viscosity of liquid alloys as follows:
Use of Thermodynamic Data to Determine Surface Tension and Viscosity of Metallic Alloys

Figure 5. Calculated results of (a) liquidus, (b) surface tension, and (c) viscosity in Sn-Sb-Bi ternary alloys obtained from a set of thermodynamic data.18

\[ \eta = A \exp\left(\frac{B}{RT}\right), \]
\[ A = 1.7 \times 10^{-7} \rho^{0.25} T_{f} M^{-1.5}, \]

\[ B = 2.65 T_{f} \rho^{0.25}, \]  

where \( M \) and \( \rho \) are atomic weight and density of liquid alloys. Equation 15 shows that the viscosity of liquid alloys is a function of liquidus temperature \( T_{f} \), which can be obtained from the phase diagram, calculated using thermodynamic data. Seetharaman et al.34,35 proposed another equation for the viscosity of liquid alloys as follows:

\[ \eta = A^* \exp\left(\frac{\Delta G^*}{RT}\right), \]

\[ A^* = 39.9 \times 10^{-11} \rho M, \]

where \( \rho = \Sigma \rho_i/\rho_i \) (\( \rho_i \) is the density of pure component \( i \)), \( M = \Sigma M_i \) (\( M_i \) is the atomic weight of pure component \( i \)), and

\[ \Delta G^* = \Sigma \Delta G_i + 3RT \Sigma N_i + \{RT \Sigma \ln N_i + C(T,N_i^2)\}, \]

where \( \Delta G_i \) is the activation energy of pure component \( i \). In this model, the activation energy of the viscosity of the liquid alloy, \( \Delta G^* \), consists of the activation energy of the pure components \( \Delta G_i \) and the excess Gibbs energy of the alloy \( G^*(T,N_i^2) \), which can also be obtained from the data in the thermodynamic databases.

Now supports HP 4192

The complete package for materials characterization

Solartron's 1296 supports HP 4192

Electrical techniques for investigating materials provide unique insights into physical and chemical behavior. They're fast, non-destructive and repeatable.

Solartron's 1296 system provides everything you need for complete characterization of almost any component or material, including:

- Wide frequency range
- DC bias and AC stimulus control to 1000V
- Support for all Solartron FRAs and Hewlett-Packard 4192
- Impedance measurement to >100T (10^12)Ω
- Complete acquisition and analysis software:
  - Experiment control
  - Data analysis and display
