Osaka University, Toyonaka

Die Abhängigkeit der Phonongeschwindigkeit und des
Rotonminimums von Temperatur wird aus dem mikroskopischen
Gesichtspunkt untersucht. Durch die Überlegung des Beitrags
aus der in der früheren Abhandlung gegebenen Wechselwirkung
zwischen Quasiteilchen finden wir, dass die Phonon-Roton-
wechselwirkung und die Roton-Rotonwechselwirkung spielen eine
grosse Rolle in der Abhängigkeit der Phonongeschwindigkeit
und des Rotonminimums von Temperatur. Das Resultat der Rechnung
stimmt mit dem Experiment überein.
§1. Introduction

The elementary excitations in liquid helium II have been the object of extensive study for many years. The phonon-roton type excitation spectrum was proposed phenomenologically by Landau \(^1\) to explain superfluid properties and thermodynamic behavior of liquid helium II below the \(\lambda\)-transition temperature. The existence of such a spectrum was demonstrated by the direct observation of single excitations from inelastic scattering of slow neutrons. \(^2\) The curve H.W. in Fig B-2 indicates the experimental results obtained by Henshaw and Woods at \(T=0^\circ\text{K}\). The experimental spectrum H.W. clearly shows the existence of the phonon-roton type excitations, as has been proposed by Landau. \(^1\)

A quantum theory of the excitations was developed by Feynman and Cohen. \(^3\) In their calculation, the excitation energy is expressed in terms of the structure factor of liquid helium. Inserting the observed results into the structure factor in the formula of the excitation energy, they obtained the excitation spectrum of which agreement with experimental one was good qualitatively but was not quantitatively.

On the other hand, progress has been made along the microscopic point of view by many authors. Bogoliubov \(^4\) derived a phonon-like elementary excitation spectrum in the low momentum region on the basis of the assumption that the finite fraction of helium atom was condensed into the zero-momentum state at \(T = 0^\circ\text{K}\), and hence the creation and the annihilation operator of helium atom at zero momentum \((a_0 \text{ and } a_0^+)\) might be replaced by \(N_0\). Parry and ter Haar \(^5\), however, have shown that the .
depletion of the zero-momentum state amounts to 270% if we take
the Brueckner-Sawada excitation spectrum which was obtained
on the basis of Bogoliubov formalism and the method of t-matrix.

Miller, Pines and Nozieres have emphasized that the
phonon-phonon interaction is indispensable to account for
the observed excitation spectrum. In the Bogoliubov formalism,
however, the assumption that \( a_0 = a_0^+ = N_0 = c\)-number ignores
the quantum fluctuation of the number of condensed atoms and
hence does not lead to a unique expression for the phonon-
phonon interaction. This difficulty has been overcome by
Sunakawa et al. by describing a Bose system in terms of the
collective variables which are appropriate to represent the
liquid system, and the theory gives a microscopic theoretical
version of the Landau quantum-hydrodynamics. The introduction
of the collective variables yields a definite expression of
the phonon-phonon interactions.

By taking into account the contributions of the definite
phonon-phonon interaction, Sunakawa, Yamasaki and the present
author have developed the theory of the excitation
energy of liquid helium II at \( T = 0\)K on the basis of the method
which is slightly different from that of the standard perturbation
theory, and obtained the convergent results for the correction of
the excitation energy. Their results of the phonon-roton type
excitation energy which are shown by the curve \( E^I_\mathbf{K} \) in Fig B-2
are in good harmony with experimental curve H.W. On the basis
of the same convergent formula for the excitation energy at \( T = 0^\circ K \),
recently, they\(^{(11)}\) have derived the multi-branch structure of
the excitation spectra which have been confirmed experimentally
by Woods et al.\(^{(12)}\).

The temperature dependence of the excitation spectrum in
liquid helium II, especially the phonon velocity and the roton
minimum, was observed experimentally by many authors. Recently
Dietrich et al.\(^{(13)}\) have made measurements of the temperature
dependence of the roton minimum by inelastic neutron scattering.
Fig. 5 shows their experimental results which indicate that
the roton-minimum decreases as temperature increases. Very
accurate measurements of the temperature dependence of the
phonon velocity have been made by Whitney and Chase by making
use of pulse techniques developed by Chase. Their results for
\( 1 \text{Mc/s} \) sound waves in helium under the saturated vapour pressure
are shown in Fig. 3, which is written in a greatly expanded scale
for the phonon velocity. A small maximum in the phonon velocity
is observed at about 0.65\(^\circ\)K. Fig. 4 shows the whole behavior of
the temperature dependence of the phonon velocity, and shows
rapid decrease of the phonon velocity in the region of temperature
from 1.5\(^\circ\)K to 2.19\(^\circ\)K. A theoretical interpretation of the
existence of a small maximum in the phonon velocity has been
given by Khalatonikov et al.\(^{(15)}\) on the basis of the phenomeno-
logical kinetic equations for the distribution functions of
phonons and rotons which are regarded as classical gases,
respectively. From microscopic point of view, ter Haar et al.\(^{(16)}\)
have developed a theory for the temperature dependence of the phonon velocity on the basis of the perturbation theory at finite temperature, by assuming Landau\(^1\) phenomenological phonon-phonon interactions. They, however, considered only a part of all diagrams which contribute to the self-energy, and the neglected diagrams give divergent results.

The purpose of this paper is to calculate the temperature dependence of the phonon velocity observed by Whitney and Chase and of the roton minimum revealed by Dietrich et al., by taking into account the effect of all diagrams which contribute to the second order self-energy. The difficulty of the divergence of the self-energy which arises from the diagrams ignored by ter Haar and others will be removed with the aid of the method proposed in the previous papers\(^9\),\(^10\) (referred to as I and II hereafter), and later by Nishiyama.\(^17\)

Section 2 is devoted to the derivation of a divergence-free formula for the excitation spectrum at finite temperature. In §3, the temperature dependence of the phonon velocity is calculated quantitatively on the basis of the formula derived in §2, and is compared with experimental results\(^14\) to have a good agreement. In §4, the temperature dependence of the roton minimum is calculated to yield also a fairly good agreement with experiments.\(^13\) In Appendix A, we shall present a résumé of the collective description. Some lemmas which are necessary for the collective description will be proved in Appendix C. The formula of the excitation energy and its results will be shown in Appendix B.
§2. The excitation energy at finite temperature

Consider a system of N interacting helium atoms of mass m enclosed in a cubic box of volume V. The Hamiltonian of this system is described in terms of the density fluctuation operator \( \rho_k \) and the velocity operator \( \nu_k \) in the following form

\[
H = E_0^B + \sum_k E_k B_k^+ B_k + \sum_{P, q \neq 0} \frac{1}{3} \Gamma_a(P, q)(B_{P+q}^+ B_{P}^+ B_{q} + B_{P} B_{q}^+ B_{P+q})
+ \sum_{P, q \neq 0} \Gamma_b(P, q)(B_{P+q}^+ B_{P}^+ B_{P} + B_{P} B_{P+q} B_{P}) (2.1)
\]

up to the order of \( N^{-\frac{1}{2}} \), where

\[
E_0^B = \frac{N(N-1)}{2 V} V(0) + \frac{1}{2} \sum_{k \neq 0} \left( E_k^B - \frac{k^2}{2m} - \frac{N}{V} V(k) \right)
\]

gives the ground state energy in the lowest approximation. The Bogoliubov excitation energy \( E_k^B \) is expressed by

\[
E_k^B = \frac{k^2}{2m} \lambda_k = \frac{k^2}{2m \sqrt{k^2 + c^2(k)}} (2.2)
\]

and the structure factor \( \lambda_k \) in the lowest approximation is

\[
\lambda_k = k \sqrt{k^2 + c^2(k)} (2.3)
\]
where

\[ C(k) = \sqrt{\frac{4N\pi m}{V}} V(k) \]

and \( V(k) \) indicates the Fourier transform of the interaction potential between two helium atoms. The functions \( \Gamma_a(p,q) \) and \( \Gamma_b(p,q) \) in (2.1) are given by

\[
\Gamma_a(p,q) = \frac{i}{8m\sqrt{\lambda p^3/4}} \left\{ (p^q)(1 + \frac{1}{\lambda p^q}) - (p^q + q^q)(1 + \frac{1}{\lambda p^q}) \right\}
\]

and

\[
\Gamma_b(p,q) = \frac{i}{8m\sqrt{\lambda p^3/4}} \left\{ (p^q)(1 - \frac{1}{\lambda p^q}) - (p^q + q^q)(1 - \frac{1}{\lambda p^q}) \right\}.
\]

The detailed derivation of the Hamiltonian (2.1) will be found in Appendix A.

The excitation energy in liquid helium II at finite temperature is calculated by making use of the method of a temperature Green-function\(^1\) defined by

\[
\tilde{G}(k, \omega; \tau) = -Tr \left( e^{i(\omega - H)} T(\tau) B_k(c) B_k^\dagger(c) \right)
\]
where

\[ B_k(\tau) = e^{H\tau} B_k e^{-H\tau}. \]

The symbol \( T_\tau \) indicates the chronological operator concerning a temperature \( T \). The second order self-energy is given by the following three diagrams shown in Fig.-1.

From three diagrams (a), (b), (c) in Fig.-1, we can readily write down the expressions

\[ \sum^{(a)}(k,\omega_n) = \frac{18}{\beta} \sum \sum (\frac{1}{3})(k,P)^2 \tilde{G}_0(P,\omega_n) \tilde{G}_0(k'P,\omega_n,\omega_k) \]  

\[ \sum^{(b)}(k,\omega_n) = \frac{2}{\beta} \sum \sum (k,P)^2 \tilde{G}_0(P,\omega_n) \tilde{G}_0(k'P,\omega_n,\omega_k) \]  

\[ \sum^{(c)}(k,\omega_n) = \frac{4}{\beta} \sum \sum \tilde{G}_0(P',\omega_n) \tilde{G}_0(k'P,\omega_n,\omega_k) \]
for the proper self-energy. In the above equations, \( \mathcal{G}_0(p, \omega_n) \) is the Fourier transform of the free temperature Green-function given by

\[
\mathcal{G}_0(p, \omega_n) = \frac{1}{i \omega_n - E^B_p} \quad (2.9)
\]

where \( \omega_n = 2 \pi n / \beta \) (\( n = 0, \pm 1, \ldots \)). After taking the summation concerning \( n \) and replacing \( i \omega_n \) by \( E^B_R + i \eta \), we get the second order excitation energy at a temperature \( T = (k_B \beta)^{-1} \) in the following form,

\[
\sum^{(a)}_{(k, E^B_R)} = -2 \sum_{p} \frac{\Gamma_a(p, p)^2}{E^B_k + E^B_p + E^B_{p+K}} - 4 \sum_{p} \frac{\Gamma_b(p, p)^2}{E^B_k + E^B_p + E^B_{p+K}} \eta(E^B_p) \quad (2.10)
\]

\[
\sum^{(b)}_{(k, E^B_R)} = 2 \sum_{p} \frac{\Gamma_b(p, p)^2}{E^B_k - E^B_p - E^B_{p+K} + i \eta} + 4 \sum_{p} \frac{\Gamma_b(p, p)^2}{E^B_k - E^B_p - E^B_{p+K} + i \eta} \eta(E^B_p) \quad (2.11)
\]

and

\[
\sum^{(c)}_{(k, E^B_R)} = -4 \sum_{p} \frac{\Gamma_b(p, p)^2}{E^B_k + E^B_p + E^B_{p+K} + i \eta} (\eta(E^B_p) - \eta(E^B_{p+K})) \quad (2.13)
\]

where

\[
\eta(E^B_p) = \frac{1}{e^{\beta E^B_p} - 1}
\]
From (2.10), (2.11) and (2.12), the excitation energy $E^F_K(T)$ at $T$ is written by

$$E^F_K(T) = E^K_B + \sum^{(a)} (K,E^K_K) + \sum^{(b)} (K,E^K_K) + \sum^{(c)} (K,E^K_K). \quad (2.14)$$

D. ter Haar and others (16) derived a similar result to calculate the absorption coefficient of the first sound in liquid helium II on the basis of the Landau phenomenological Hamiltonian. They consider only the effect of $\sum^{(c)} (K,E^K_K)$ in (2.14) and do not take the contributions from $\sum^{(a)} (K,E^K_K)$ and $\sum^{(b)} (K,E^K_K)$ into consideration. Since $\sum^{(a)} (K,E^K_K)$ and $\sum^{(b)} (K,E^K_K)$ play a very important role in the temperature dependence of the phonon velocity and the roton minimum, as will be seen later, we must consider the effect of the new terms $\sum^{(a)} (K,E^K_K)$ and $\sum^{(b)} (K,E^K_K)$ in (2.14). However the first terms on the right hand side of (2.10) and (2.11) are strongly divergent. In order to avoid this serious difficulty, we make use of the method proposed in the previous paper (9). In this paper, the excitation spectrum at zero temperature has been calculated to yield a convergent result which is in good agreement with the experiment. (2) Nishiyama (17) derived later essentially the same result by making use of the ordinary perturbation formalism. Since the method of Nishiyama is more convenient for the present approach than the original method in I, we use his method to overcome the difficulty.

Let us now introduce the Feynman energy $E^F_K (3)$ defined by

$$E^F_K = \frac{k^2}{2m} |S(K)|^2. \quad (2.15)$$
$S(R)$ is the structure factor of liquid helium II at $0^\circ$K:

$$S(R) = \frac{\langle G \mid \rho_R \phi_R^\dagger \mid G \rangle}{\langle G \mid G \rangle} = n_R \langle G \mid (B_R^+ B_R^-) (B_R^+ B_R^-) \mid G \rangle / \langle G \mid G \rangle \quad (2.16)$$

where $\mid G \rangle$ denotes the ground state of the total Hamiltonian (2.1). After the straightforward calculation, we have

$$S(k) = n_R + 4 n_R \sum_P \left\{ \frac{\Gamma_a(k, P)^2}{(E_R^B + E_P^B + E_{P+k}^B)^2} + \frac{\Gamma_a(k, P) \Gamma_b(k, P)}{E_R^B (E_R^B + E_P^B + E_{P+k}^B)} \right\}. \quad (2.17)$$

Substitution of (2.17) into (2.15) gives

$$E_R^F = E_R^B - 4 E_R^B \sum_P \left\{ \frac{\Gamma_a(k, P)^2}{(E_R^B + E_P^B + E_{P+k}^B)^2} + \frac{\Gamma_a(k, P) \Gamma_b(k, P)}{E_R^B (E_R^B + E_P^B + E_{P+k}^B)} \right\}$$

in the second-order approximation. From (2.14) and (2.18) we get

$$E_R(t) = E_R^F + 2 \sum_P \frac{\Gamma_a(k, P)(E_R^B - E_P^B - E_{P+k}^B) + \Gamma_b(k, P)(E_R^B + E_P^B + E_{P+k}^B)^2}{E_R^B (E_R^B + E_P^B + E_{P+k}^B)^2}$$

$$- 4 \sum_P \frac{\Gamma_a(k, P)^2}{E_R^B + E_P^B + E_{P+k}^B} \{ n(E_P^B) \}$$

$$- 4 \sum_P \frac{\Gamma_b(k, P)^2}{E_R^B + E_P^B + E_{P+k}^B} \{ n(E_P^B) \}$$

$$- 4 \sum_P \frac{\Gamma_b(k, P)^2}{E_R^B + E_P^B + E_{P+k}^B + \eta} \{ n(E_P^B) \}$$

$$- 4 \sum_P \frac{\Gamma_b(k, P)^2}{E_R^B + E_P^B + E_{P+k}^B + \eta} \{ n(E_P^B) \}.$$  \quad (2.19)
The second term on the right hand side of (2.19) is independent of temperature $T$ and gives the correction term for the Feynman energy $E^F_R$ at zero temperature. This correction term is strongly convergent in contrast to the first terms in $\sum^{(a)}_\alpha (R, E^B_R)$ and $\sum^{(b)}_\beta (R, E^B_R)$. On the other hand, the third, fourth and fifth terms on the right hand side of (2.19) give the temperature dependence of the excitation spectrum.
§3. The temperature dependence of the phonon velocity

In this section we shall investigate the temperature dependence of the phonon velocity on the basis of the formula (2.19) derived in the preceding section. The temperature dependent part $\delta E_k(T)$ in (2.19) is given by

$$\delta E_k(T) = \delta E_k^{(0)}(T) + \delta E_k^{(b)}(T) + \delta E_k^{(c)}(T)$$

where

$$\delta E_k^{(0)}(T) = -4 \sum_{\tilde{P}} \frac{\Gamma_b(k,\tilde{P})^2}{E_k^B + E_{\tilde{P}}^B + E_{\tilde{P}^R}^B} \eta(E_{\tilde{P}^R}^B)$$

$$\delta E_k^{(b)}(T) = 4 \sum_{\tilde{P}} \phi \frac{\Gamma_b(k,\tilde{P})^2}{E_k^B - E_{\tilde{P}}^B - E_{\tilde{P}^R}^B} \eta(E_{\tilde{P}}^B)$$

and

$$\delta E_k^{(c)}(T) = -4 \sum_{\tilde{P}} \phi \frac{\Gamma_{\tilde{P}}(k,\tilde{P})^2}{E_k^B + E_{\tilde{P}}^B - E_{\tilde{P}^R}^B} \left\{ \eta(E_{\tilde{P}}^B) - \eta(E_{\tilde{P}^R}^B) \right\}$$

on taking the real part of (2.19). The symbol $\phi$ indicates to take the principal values for the integrals. In order to proceed further, we replace $E_k^B$ involved on the right hand side of (3.2), (3.3) and (3.4) by the experimental excitation spectrum $E_k$ at zero temperature. This replacement may be plausible if we take the higher order corrections into consideration.
The deviation of the phonon velocity from that of zero temperature is given by

\[ \delta c(T) = \delta c^{(a)}(T) + \delta c^{(b)}(T) + \delta c^{(c)}(T) \]

\[ = \lim_{k \to 0} \frac{1}{k} \left\{ \delta E_k^{(a)}(T) + \delta E_k^{(b)}(T) + \delta E_k^{(c)}(T) \right\}. \tag{3.5} \]

We now first calculate the contribution from \( \delta c^{(a)}(T) \) and \( \delta c^{(b)}(T) \). Since we can put

\[ E_k \to \frac{c k}{2 m} \]

and

\[ \lambda_k \to \frac{k}{c} \tag{3.6} \]

in the limit of \( k \to 0 \), we have

\[ \delta c^{(a+b)}(T) = \delta c^{(a)}(T) + \delta c^{(b)}(T) \]

\[ = -2 \left\{ \frac{1}{2} \frac{4}{(8m)^2} \frac{1}{N} \frac{1}{c} \sum_{\mathbf{P}} f(\mathbf{P}) \right\}, \tag{3.7} \]

\[ f(\mathbf{P}) = \frac{\lambda^2_{\mathbf{P}} (1 + \frac{1}{\lambda^2_{\mathbf{P}}})^2 \mathbf{P}^4}{E_{\mathbf{P}} (e^{\beta E_{\mathbf{P}}} - 1)} \tag{3.8} \]

where \( c = 3^{2/3} \) is the phonon velocity at zero temperature. In order to carry out the integration in (3.7), we separate the region of the momentum integration by an appropriate
momentum $P_c$ into two parts, that is, the phonon region and the roton region. Then we have

$$\delta C^{(a+b)}(T) = -\frac{4}{(8m)^2} \frac{V}{N} \frac{1}{c(2\pi)^2} \left\{ \int_0^{P_c} f(p)p^2dp + \int_{P_c}^{\infty} f(p)p^2dp \right\}. \tag{3.9}$$

In the phonon region, we can replace $E_p$ and $\lambda_p$ by $cp/2m$ and $p/c$, respectively, and we can extend the finite range of the integration to infinity without introducing any appreciable error in virtue of the existence of the statistical factor $n(E_p)$, and we have the contribution $\delta C^{(a+b)}_{(ph)}$ from the phonon region as

$$\delta C^{(a+b)}_{(ph)}(T) = -\frac{\pi^2}{120} \frac{V}{N} \frac{c^2}{(2\pi)^3} \frac{(k_B)^4}{k_B^2m^3}. \tag{3.10}$$

where we have used the fact that $1 \gg \lambda_p$. In the roton region, we can put

$$\lambda_p \simeq 1$$

and

$$E_p \simeq \Delta + \frac{1}{2\mu}(p-k_o)^2. \tag{3.11}$$

where

$$\Delta = 12 \times 10^{-16} \text{ mG},$$

$$\mu = 10^{-24} \text{ g},$$

and

$$k_o = 1.9 \text{ Å}^{-1}.$$
By making use of (3.11) and by retaining the dominant terms, we have

\[
\delta C_{\text{rot}}^{(a+b)}(T) \approx \frac{1}{2} \left\{ \frac{4}{(3m)^2 N} \frac{V}{C^2} \frac{4k_b^2}{\Delta} e^{-\frac{\beta a}{2(2\pi)^2}} \int_{-\infty}^{+\infty} \frac{dp}{p} e^{-\frac{p^2}{2\mu}} \right\}
\]

\[
= -\frac{1}{2\pi^{3/2} N} \frac{V}{C^2} \frac{k_b T}{\Delta} \sqrt{\frac{k_b T}{\mu}} \beta \Delta \cdot e^{-\frac{\Delta}{k_b T}} \tag{3.12}
\]

where we have used the fact that

\[
\int_{-\infty}^{+\infty} \frac{dp}{p} e^{-\frac{p^2}{2\mu}} \approx \int_{-\infty}^{+\infty} dp e^{-\frac{p^2}{2\mu}} = \sqrt{2\pi \mu k_b T} \tag{3.13}
\]

Collecting (3.10) and (3.12), we can write

\[
\delta C_{\text{rot}}^{(a+b)}(T) = -\frac{\pi^2 V}{120 N} \frac{C^2}{(3m)^3} \left( \frac{k_b T}{h^2} \right)^4 - \frac{1}{2\pi^{3/2} N} \frac{V}{C^2} \frac{k_b T}{\Delta} \sqrt{\frac{k_b T}{\mu}} \beta \Delta \cdot e^{-\frac{\Delta}{k_b T}} \tag{3.14}
\]

We next calculate \( \delta C^{(c)}(T) \) in (3.5). In the limit of \( k \to 0 \), the energy denominator and the statistical factor in (3.4) vanish simultaneously. Therefore we must expand them around \( |\mathbf{\hat{k}}| = 0 \), and retain only nonvanishing lowest terms. In the phonon region \( |\mathbf{p}| \sim 0 \), we can write

\[
\delta C^{(c)}(T) = -\frac{1}{(2\pi)^2 (3m)^2 N} \int d\mathbf{p} \int_{-1}^{1} \frac{d\mu}{c^{2m} + |\mathbf{p}|^2} e^{-\frac{\beta a}{2(2\pi)^2}} |\mathbf{p}| \mu \beta^2 \langle \mu \rangle (\langle \mu \rangle) (\langle \mu \rangle) \tag{3.15}
\]
where use is made of (3.6) in the integrand and the vertex function \( \Gamma_b(p, k) \) is approximated only by the term which have lowest power in \( p \). The angular integration gives

\[
\Xi C(T) = -\frac{1}{(2\pi)^2} \frac{4}{(8\pi^2)N} \int_0^\infty dp p^2 \left\{ 20.6 - 9 \ln \left( \frac{\gamma}{p^2} \right) \right\} \mathcal{N}(p) \mathcal{N}(p+1)
\]

(3.16)

where we have used the relation

\[
|\vec{p} \cdot \vec{E}_p| = \frac{C}{2m} (1 - 3\gamma p^2)
\]

and the expansion coefficient \( \gamma = 2.2 \times 10^{37} \text{g}^{-2} \text{cm}^{-2} \text{sec}^2 \) is obtained with the aid of the energy spectrum calculated in the previous papers I and II. Carrying out the integration in (3.16), we find

\[
\Xi C(T) = -\frac{\pi^2}{60} \frac{C}{N} \left( \frac{k_B T}{\sqrt{m}} \right)^4 \left\{ 20.6 - \frac{18}{\ln \left( \frac{\gamma}{p^2} \right) \left( \frac{C}{k_B T} \right)^3} \right\}
\]

(3.17)

where we have replaced \( p \) by \( 3k_B T/C \) in the logarithmic term of the integrand of (3.16), and the other factor in the integrand of (3.16) has a maximum value for this value of \( p \). On the other hand, the contribution of the integral from the roton region is negligibly small. This comes from the fact that the leading term of the integrand in (3.4) is proportional to \( (p-k_o) \), since the order of magnitude of the statistical factor in the roton region \( p \approx k_o \) is given by \( \frac{p}{k_B T} (p-k_o) \) and the energy denominator is \( Ck_B T \).
Collecting (3.14) and (3.17), we have the final result for the temperature dependent part of the phonon velocity;

\[ \Delta C(T) = \Delta C^{(a+b)}(T) + \Delta C^{(c)}(T) \]

\[ = -\frac{r^2 V}{120 N} \frac{C^2 \left( k_B T \right)^4}{(\frac{C}{\sqrt{m}})^2} - \frac{1}{2\pi^2 N} \frac{V k_B}{C^2} \left( \frac{C}{\sqrt{m}} \right)^2 \frac{k_B T}{\sqrt{k_B^2 \mu}} e^{-\frac{\Delta}{k_B T}} \]

\[ - \frac{r^2 V}{60 N} \frac{C^2 \left( k_B T \right)^4}{(\frac{C}{\sqrt{m}})^2} \left\{ 20.6 - 18 \ln \left( \frac{5}{278} \frac{1}{C k_B T} \right) \right\} \quad (3.19) \]

Introducing the numerical values

\[ C = 3 \AA^{-1} \]

\[ \frac{V}{N} = 45.8 \AA^3 \]

and

\[ \gamma = 2.2 \times 10^{37} \text{ g}^{-2} \text{ cm}^{-2} \text{ sec}^{-2} \]

we have the result

\[ \Delta C(T) = 10.4 T^{\frac{3}{4}} \ln \left( \frac{31}{T} \right) - 5.7 \times 10^4 T^{\frac{8.6}{T}} e \left( \frac{\text{cm}}{\text{sec}} \right) \quad (3.19) \]

In the expression (3.19), the first term on the right hand side is the contribution from the phonon region and the second term comes from the effect of the roton region. The first term gives increase of the phonon velocity as temperature rises, and the second term, on the other hand, decreases the phonon
velocity. This behavior of the second term is indispensable for explaining the experimental results of the temperature dependence for the phonon velocity which show characteristic decrease. We should note here that this second term comes from (3.1) and (3.2) which are not considered in the theory of ter Haar et al.. The numerical result of (3.19) is shown in Table-I, and compared with the experimental result(14) in Fig.-3 and Fig.-4.

| Table I | Fig. 3 | Fig. 4 |

Although the position of the maximum point of the theoretical curve is slightly larger than the experimental one in Fig.-3, the whole behavior of the theoretical curve is very similar to the measured one.

In conclusion, we can see that the phonon velocity increases slightly due to the effect of the phonon-phonon interaction up to 0.6°K, and the phonon-roton interaction becomes effective above 0.6°K to decrease strongly the phonon velocity. We can further expect that the phonon-roton interaction also plays an important role in the temperature dependence of the absorption coefficient of the first sound in liquid helium II, and this problem is now under consideration.
§4. The temperature dependence of the roton minimum

In this section we shall study the temperature dependence of the roton minimum $\Delta$. The deviation of the roton minimum $\delta \Delta(T)$ from that at zero temperature is described from (3.2), (3.3) and (3.4) by

$$\delta \Delta(T) = \delta \Delta^{(a)}(T) + \delta \Delta^{(b)}(T) + \delta \Delta^{(c)}(T),$$

$$\delta \Delta^{(a)}(T) = -4 \sum_{P} \frac{\delta P_{0}(k_{0},p)^{2}}{\Delta + E_{P} + E_{P + k_{0}}} \eta(E_{P}),$$

$$\delta \Delta^{(b)}(T) = 4 \sum_{P} \frac{\delta P_{0}(k_{0},p)^{2}}{\Delta - E_{P} - E_{P + k_{0}}} \eta(E_{P}),$$

and

$$\delta \Delta^{(c)}(T) = -4 \sum_{P} \frac{\delta P_{0}(P,k_{0})^{2}}{\Delta + E_{P + k_{0}} - E_{P}} \left\{ \eta(E_{P}) - \eta(E_{P + k_{0}}) \right\}.$$  

where

$$|k_{0}| = k_{0},$$

$$E_{k_{0}} = \Delta,$$

and

$$\lambda_{k_{0}} \approx 1.$$  

As in the case of the phonon velocity, we separate the region of the momentum integrations of (4.2), (4.3) and (4.4) into two parts, that is, the phonon region and the roton region.

We first consider the contributions from the phonon region ($p \sim 0$) by using the following approximated relations;
\[ \Gamma_a(k, p)^2 \approx \frac{1}{8m^2 N} \frac{1}{4k^2} \rho \]

\[ E_{k_0} + E_p + E_{p+k_0} \approx 2\Delta \]

\[ \Gamma_b(k, p)^2 \approx \frac{1}{8m^2 N} 4ck^2 \rho \cos^2 \theta \]

\[ E_{k_0} - E_p - E_{p+k_0} \approx -\frac{cP}{2m} \]

\[ \Gamma_b(p, k)^2 \approx \frac{1}{8m^2 N} \frac{4k^4}{c} \rho \]

and

\[ E_{k_0} + E_{p+k_0} - E_p \approx 2\Delta. \]

The substitution of the relations in (4.6) into (4.2), (4.3) and (4.4) and the momentum integrations give

\[ \Delta^{(a)}(T) = -\frac{\pi^2 V}{60 N} \frac{k_3^4}{c^2} \frac{(k_bT)^4}{(2\pi)^4} \Delta \]  

\[ \Delta^{(b)}(T) = -\frac{A}{6\pi^2 N} \frac{V}{c} \frac{k_3^2}{c^2} \frac{(k_bT)^3}{(2\pi)^2} \]

and

\[ \Delta^{(c)}(T) = -\frac{\pi^2 V}{60 N} \frac{k_3^4}{c^2} \frac{(k_bT)^4}{(2\pi)^4} + \frac{9}{4\pi^2 N} \frac{V}{c} \frac{k_3^2}{c^2} \frac{(k_bT)^2}{\Delta} \frac{(k_3^2)^2}{(2\pi)^2} \frac{\Delta}{k_3T} \]
where in (4.8)
\[ A = \int_0^{\infty} dx \frac{x^2}{e^{x^2} - 1} \approx 2.4 , \]
and in the second term of (4.9) we have used the following approximation:
\[ e^{-\frac{1}{2\mu}} (|p + k_o| - k_o)^2 \approx e^{-\frac{p^2}{2\mu}} . \]  

Collecting (4.7), (4.8) and (4.9), we have the expression for the temperature dependence of the roton minimum

\[ \Delta \Delta'_{q_{st}}(T) = -\frac{4^4 \pi}{6 \pi^2 N} C k_o^2 \frac{(k_B T)^3}{(C^2 \bar{m})^2} - \frac{\pi^2}{30} \frac{\pi^4}{N C} \frac{(k_B T)^4}{(C^2 \bar{m})^4} \]
\[ + \frac{9}{8 \pi^2 N C^2} \frac{C^2}{\Delta} \frac{(k_B T)^2}{(k_B T)^2} e^{-\frac{\Delta}{k_B T}} . \]

from the phonon region.

We next calculate the contributions from the roton region (\(|p| \sim k_o\)) by using (4.5) as the approximated relations for \(E_p\) and \(\lambda_p\) in the integrands of (4.2), (4.3) and (4.4). The contributions from the roton region are given by

\[ \Delta \Delta'_{q_{st}}^{(w)}(T) = -\frac{4^4 \pi}{(8 \pi m)^2 N} \sum_p \frac{\lambda_{p + k_o} (2 k_o^2 + (p + k_o)^2)^2}{2 \Delta + E_{p + k_o}} \frac{1}{(p - k_o)^2} \]
\[
\delta \Delta_\text{rot(b)}^{(b)}(\tau) = -\frac{4}{(\hbar m)^2 N} \sum_{\mathbf{P}} \frac{\lambda_{\mathbf{P}+\mathbf{k}_o}(\mathbf{P}+\mathbf{k}_o)^4}{E_{\mathbf{P}+\mathbf{k}_o}} \mathcal{N}(\Delta + \frac{1}{2\mu}(\mathbf{P}+\mathbf{k}_o)^2) \quad (4.13)
\]

and

\[
\delta \Delta_\text{rot(c)}^{(c)}(\tau) = -\frac{4}{(\hbar m)^2 N} \sum_{\mathbf{P}} \frac{\lambda_{\mathbf{P}+\mathbf{k}_o}(\mathbf{P}+\mathbf{k}_o)^4}{E_{\mathbf{P}+\mathbf{k}_o}} \left\{ \mathcal{N}(\Delta + \frac{1}{2\mu}(\mathbf{P}+\mathbf{k}_o)^2) - \mathcal{N}(E_{\mathbf{P}+\mathbf{k}_o}) \right\} \quad (4.14)
\]

where we have used the fact that $|\mathbf{p}| \sim k_0$. The integrations on the right hand side of (4.12), (4.13) and (4.14) are to be carried out for two regions when $|\mathbf{P}+\mathbf{k}_o|$ is in the phonon region and when it is in the roton region, respectively. After the integrations for these regions, we obtain

\[
\delta \Delta_\text{rot(a)}^{(a)}(\tau) = -\frac{3}{8\pi^2 N} \frac{V \kappa^3}{\Delta} \sqrt{\frac{k_8 T}{k_8/2\mu}} \frac{\Delta}{k_8 T} \frac{\Delta}{k_8 T} \quad (4.15)
\]

\[
\delta \Delta_\text{rot(b)}^{(b)}(\tau) = -\frac{1}{8\pi^2 N} \frac{V \kappa^3}{\Delta} \sqrt{\frac{k_8 T}{k_8/2\mu}} \frac{\Delta}{k_8 T} \quad (4.16)
\]

\[+ \text{(small terms)} \]
and

\[ \delta \Delta_{\text{rot}}^{(e)}(T) \approx \text{(small terms)} \]

for the contributions from the roton region. In (4.15) and (4.16), we have written down explicitly only the leading terms, and the other small terms are negligible compared with the leading terms.

Collecting (4.11), (4.15) and (4.16), we have the final result for the deviation of the roton minimum from that at zero temperature;

\[
\delta \Delta(T) = -\frac{2.4}{6\pi^2 N} \frac{v}{c^2} k_0^2 \left( \frac{k_0 T}{c^2} \right)^3 - \frac{\pi^2}{30 N} \frac{v}{C^2} \frac{k_0^2}{(c^2 T)^\Delta} \frac{k_0}{k_0^2 T} \left( \frac{k_0 T}{c^2} \right)^\Delta
\]

By using the numerical values of the constants \( \Delta, c, v/N \) and \( k_0 \) given in the preceding section, we obtain the result

\[
\delta \Delta(T) = -9.5 \times 10^{-11} T^3 - 3.5 \times 10^{-11} T^4 - 17.5 \times 10^{-15} T e^{-2.6/T} \text{ (and)} \quad (4.18)
\]

---

Fig. 5

Table II
The first and second terms in (4.18) are the contributions from the phonon region to the roton minimum, and the third term in (4.18) is the correction term from the roton region. From (4.18), the numerical values for the roton minimum

\[ \Delta(T) = \Delta + \delta \Delta(T) \]

are shown in Table-2 and compared with experiments \(^{(13)}\) in Fig.-5, from which we find that the theoretical result is in fairly good agreement with the experimental one.

In conclusion we can see that the roton minimum gradually decreases due to the effect of the roton-phonon interaction up to \(0.7^\circ\)K, and begins to decrease rapidly above \(0.7^\circ\)K by the effect of the roton-roton interaction.
Appendix A

Collective description and phonon-phonon interaction

We consider a system of \( N \) interacting helium atoms of mass \( m \) enclosed in a cubic box of volume \( V \) at \( T = 0^\circ K \). The Hamiltonian for our system is given by

\[
H = \sum_{k} \frac{k^2}{2m} a_k^+ a_k + \frac{1}{2} \sum_{k, l, l'} \frac{V(k)}{V} a_k^+ a_{l'} a_{l+k} a_{-k-l}
\]

where \( V(k) \) is the Fourier transform of the effective interatomic potential \( V(x) \). The commutation relations are given by

\[
[a_k, a_{k'}^+] = \delta_{k, k'}, \quad [a_k, a_{k'}] = [a_{k'}, a_k] = 0 .
\]

In this appendix, we rewrite the original Hamiltonian (A-1) in terms of the collective variables which are appropriate to describe the collective behavior of the system. As the collective variables, we first introduce the density fluctuation operator and the current operator defined by

\[
\rho_R = \sum_P a_{p+R}^+ a_p
\]

and

\[
c_{R} = \sum_P a_{p-k_2}^+ a_{p+k_2} .
\]
From (A-2) and (A-3), we can readily derive the following commutation relations,

$$\left[ p_k, p_{k'} \right] = 0, \quad \left[ \tilde{q}_k, p_{k'} \right] = k' \delta_{k, k'}$$

and

$$\left[ q_{k(1)}^{(1)}, q_{k'}^{(1)} \right] = \left( q_{k+1}^{(1)}, q_{k+1}^{(1)} - q_{k+1}^{(1)}, q_{k+1}^{(1)} \right) \right), \quad (A-4)$$

where

$$\tilde{q}_k = (q_k^{(1)}, q_k^{(2)}, q_k^{(3)}) \right), \quad \mathbf{k} = (k_1, k_2, k_3) .$$

One cannot treat $p_k$ and $\tilde{q}_k$ as a canonical set of variables because of the fact that the commutator between $\tilde{q}_k$ and $p_{k'}$ is not a c-number, and the third commutation relation in (A-4) does not vanish even for the case $k = k'$. As the canonical variables for $p_k$, however, we can introduce the new collective variables, i.e. the velocity operator $\tilde{v}_k$, defined by the integral equation

$$\tilde{v}_k = \frac{1}{N} \tilde{q}_k - \frac{1}{N} \sum_{\mathbf{k} \neq \mathbf{k}} \frac{p_{k'} \tilde{v}_{k'}}{p_{k'}}, \quad (A-5)$$

where $\tilde{N} = p_0 = \sum_{\mathbf{p}} a_\mathbf{p}^\dagger a_\mathbf{p} .$

From (A-4) and (A-5), we can prove the commutation relations

$$\left[ \tilde{v}_{k'}, p_{k'} \right] = k' \delta_{k, k'}$$

and

$$\left[ \tilde{v}_{k(1)}^{(1)}, \tilde{v}_{k'}^{(1)} \right] = 0 \right), \quad (A-6)$$
where the last commutation relation in (A-6) will be derived in the appendix C. In contrast to the case of \( \hat{q}_k \), the new variables \( \hat{v}_k \) do commute exactly with \( \hat{q}_k \), for \( k \neq k' \), and we can rewrite (A-5) in the following form:

\[
\vec{v}_k = \frac{1}{N} \hat{q}_k - \frac{1}{N} \sum_{p \neq k} \vec{v}_p \rho_{p-k} .
\]  

(A-7)

It should be noted that the commutation relations (A-6) coincide precisely with those assumed by Landau\(^{(1)}\), except the fact that the second commutation relation in (A-6) vanishes.

In order to express the Hamiltonian (A-1) in terms of the collective variables, we now introduce a projection operator defined by

\[
P(R-k\prime) = \sum_{p} \rho_{p+k\prime} \frac{1}{N} \rho_{p+k\prime} - \sum_{m \neq p} \rho_{m+k} \frac{1}{N} \rho_{m+k} \rho_{m+k\prime} + \cdots ,
\]

(A-8)

which will be proved in (C-8) to be

\[
P(R-k\prime) = \mathbb{1} \delta_{R,k\prime}
\]

(A-9)

for the case of Bose system. Noting the relation (A-9), we insert (A-8) into (A-1) and hence the kinetic energy \( T \) is written as

\[
T = \frac{1}{2m} \left\{ \sum_{k,k\prime} \frac{1}{N} k a^+_k a_{k+k\prime} a^+_k a_{k+k\prime} - \sum_{q \neq p} \sum_{k,k\prime} k a^+_k a_{p+p+k\prime} \frac{1}{N} \rho_{p-p+k\prime} \frac{1}{N} k a^+_k a_{q+q+k\prime} \cdots \right\} .
\]

(A-10)

Introducing the relations

\[
\sum_{k} k a^+_k a_k = \hat{q}_p - \frac{1}{2} \rho_{p-p} \rho_{p-p}
\]
and

$$\sum_k k q_k^+ a_{k+p} = \frac{\vec{p}}{\alpha} - \frac{1}{\alpha} P q P$$  \hspace{1cm} (A-11)$$

into (10), we obtain

$$T = \frac{1}{2m}\left\{ \sum_P \frac{1}{N} \frac{\vec{q}}{p} - \sum_{q+p} \frac{1}{N} p q \frac{1}{N} \frac{\vec{q}}{q} + \cdots \right\} + \frac{1}{2m}\left\{ \sum_P \frac{P^2}{4} \frac{1}{N} p - \sum_{q+p} \frac{(P q)}{4} \frac{1}{N} p q \frac{1}{N} q + \cdots \right\} - \frac{1}{2m}\left\{ \sum_P \frac{P}{\alpha} \left( \frac{\vec{q}}{p} \frac{1}{N} p - \frac{1}{N} \frac{\vec{q}}{q} \right) - \sum_{q+p} \frac{P}{\alpha} \left( \frac{\vec{q}}{q} \frac{1}{N} q - \frac{1}{N} \frac{\vec{q}}{q} \right) + \cdots \right\}$$  \hspace{1cm} (A-12)$$

In order to express (A-12) in terms of the velocity operator defined by (A-5), let us consider in detail the first term on the right-hand side of (A-12). The first series can be transformed into the following form:

$$\frac{1}{2m}\left\{ \sum_P \frac{\vec{q}}{p} \frac{1}{N} p - \sum_{q+p} \frac{1}{N} p q \frac{1}{N} \frac{\vec{q}}{q} + \cdots \right\} = \frac{1}{2m}\left\{ \sum_{P', P''} \vec{v}_{P'} \frac{1}{N} p_{P'} \frac{1}{N} p_{P''} \vec{v}_{P''} - \sum_{q+p} \sum_{P', P''} \vec{v}_{P'} \frac{1}{N} p_{P'} \frac{1}{N} p_{q} \frac{1}{N} p_{q} \vec{v}_{P''} + \cdots \right\}.$$
Noting that \( \rho_0 = \tilde{N} \), we divide each term of the last expression into two parts, i.e. the part of \( \rho' = \rho \) and that of \( \rho' + \rho \), and obtain

\[
\frac{1}{2m} \left\{ \sum_{\mathbf{p}} \frac{\mathbf{p}^2}{\mathbf{p} + \mathbf{p}'} \frac{\mathbf{p}^2}{\mathbf{p} + \mathbf{p}'} - \sum_{\mathbf{i} + \mathbf{p}} \frac{\mathbf{p}^2}{2N} \frac{\mathbf{p}^2}{2N} + \cdots \right\}
\]

\[
= \frac{1}{2m} \left\{ \sum_{\mathbf{p}, \mathbf{p}''} \frac{\mathbf{p}^2}{\mathbf{p} + \mathbf{p}''} \frac{\mathbf{p}^2}{\mathbf{p} + \mathbf{p}''} + \sum_{\mathbf{p}, \mathbf{p}''} \frac{\mathbf{p}^2}{\mathbf{p} + \mathbf{p}''} \frac{\mathbf{p}^2}{\mathbf{p} + \mathbf{p}''} - \sum_{\mathbf{i} + \mathbf{p}, \mathbf{p}''} \frac{\mathbf{p}^2}{\mathbf{p} + \mathbf{p}''} \frac{\mathbf{p}^2}{\mathbf{p} + \mathbf{p}''} - \sum_{\mathbf{i} + \mathbf{p}, \mathbf{p}''} \frac{\mathbf{p}^2}{\mathbf{p} + \mathbf{p}''} \frac{\mathbf{p}^2}{\mathbf{p} + \mathbf{p}''} \right\} + \cdots \}
\]

All the terms cancel out except the first term on the right hand side of \((A-13)\), and we have

\[
\frac{1}{2m} \left\{ \sum_{\mathbf{p}} \frac{\mathbf{p}^2}{\mathbf{p} + \mathbf{p}'} \frac{\mathbf{p}^2}{\mathbf{p} + \mathbf{p}'} - \sum_{\mathbf{i} + \mathbf{p}} \frac{\mathbf{p}^2}{2N} \frac{\mathbf{p}^2}{2N} + \cdots \right\} = \frac{1}{2m} \sum_{\mathbf{p}, \mathbf{i}} \frac{\mathbf{p}^2}{\mathbf{p} + \mathbf{i}} \frac{\mathbf{p}^2}{\mathbf{p} + \mathbf{i}}. \quad (A-14)
\]

In the quite similar way, we obtain

\[
- \frac{1}{2m} \left\{ \sum_{\mathbf{p}} \frac{\mathbf{p}^2}{\mathbf{p} + \mathbf{p}'} \frac{\mathbf{p}^2}{\mathbf{p} + \mathbf{p}'} - \sum_{\mathbf{i} + \mathbf{p}} \frac{\mathbf{p}^2}{2N} \frac{\mathbf{p}^2}{2N} + \cdots \right\} = - \frac{1}{2m} \sum_{\mathbf{p}, \mathbf{i}} \frac{\mathbf{p}^2}{\mathbf{p} + \mathbf{i}} \frac{\mathbf{p}^2}{\mathbf{p} + \mathbf{i}} \quad (A-15)
\]

with the aid of the commutation relations \((A-6)\). The interaction energy is expressed by
where \( N \) is the total number of the particles in our system and the operator \( \hat{N} \) has been replaced by a c-number \( N \) by virtue of the fact that the total number of the particles is always conserved.

Collecting (A-14), (A-15) and (A-16), we find the Hamiltonian expressed in terms of the collective variables in the following form:

\[
H = \left\{ \frac{N(N-1)}{2V} \nu(0) - \frac{N}{2V} \sum_{k \neq 0} \nu(k) + \frac{1}{2} \sum_{k \neq 0} \frac{\nu(k)}{V} \dot{p}_k \dot{p}_k \right\} + \frac{1}{2N} \sum_{k} \left\{ \frac{N}{2m} \vec{p}_k \cdot \vec{v}_k - \frac{1}{8mN} \nu(k) \hat{p}_k \hat{p}_k \right\} + \frac{1}{2N} \sum_{\vec{p}, \vec{q}} \left\{ \frac{1}{2m} \vec{p}_\vec{p} \cdot \vec{v}_\vec{q} \vec{v}_\vec{q} + \frac{1}{8mN^2} (\vec{p}_\vec{p} \vec{p}_\vec{p} + \vec{p}_\vec{p} \vec{q}_\vec{q}) \right\} - \cdots .
\]  

(A-17)

The second term of the Hamiltonian (A-17) can be regarded as the free part, and the third and higher terms give the phonon-phonon interactions.

If we introduce the operators \( \hat{B}_k \) and \( \hat{B}_k^+ \) by

\[
\hat{p}_k = \sqrt{N} \lambda R (\hat{B}_k + \hat{B}_k^+) \quad \text{and} \quad \hat{v}_k = \frac{1}{2 \sqrt{N} \lambda R} (\hat{B}_k - \hat{B}_k^+) ,
\]  

(A-18)

the new operators satisfy the commutation relations
\[ [B_k, B_k^+] = 0, \quad [B_{k'}, B_{k'}^+] = 0 \]

and

\[ [B_k, B_{k'}^+] = \delta_{k,k'}, \quad (A-19) \]

where

\[ \lambda_k = k \sqrt{E + C(k)} \quad , \quad k = \|k\| \quad (A-20) \]

and

\[ C(k) = \sqrt{\frac{4Nm}{V} \psi(k)} \quad (A-21) \]

Inserting (A-18) into (A-17), we have the new representation of the Hamiltonian:

\[ H = H_0 + H_I \]

\[ H_0 = E_0^B + \sum_k E_k^B B_k^+ B_k \]

and

\[ H_I = \frac{1}{8mN} \sum_{\mathbf{p}^2} (\mathbf{p} \cdot \mathbf{q}) \lambda_{\mathbf{p}^2} \lambda_{\mathbf{q}^2} \left( \frac{1+\lambda_{\mathbf{p}^2}}{\lambda_{\mathbf{p}^2}^2} (1+\lambda_{\mathbf{q}^2}) \right) \{ B_{\mathbf{q}}^+ B_{\mathbf{p}}^+ B_{\mathbf{p}} B_{\mathbf{q}} + B_{\mathbf{q}}^+ B_{\mathbf{p}}^+ B_{\mathbf{p}} B_{\mathbf{q}} + B_{\mathbf{q}}^+ B_{\mathbf{p}}^+ B_{\mathbf{p}} B_{\mathbf{q}} \} \]

\[ + \frac{1}{8mN} \sum_{\mathbf{p}^2} (\mathbf{p} \cdot \mathbf{q}) \lambda_{\mathbf{q}^2} \lambda_{\mathbf{p}^2} \left( \frac{1-\lambda_{\mathbf{p}^2}}{\lambda_{\mathbf{p}^2}^2} (1-\lambda_{\mathbf{q}^2}) \right) \{ B_{\mathbf{q}}^+ B_{\mathbf{p}}^+ B_{\mathbf{p}} B_{\mathbf{q}} + B_{\mathbf{q}}^+ B_{\mathbf{p}}^+ B_{\mathbf{p}} B_{\mathbf{q}} + B_{\mathbf{q}}^+ B_{\mathbf{p}}^+ B_{\mathbf{p}} B_{\mathbf{q}} \}, \quad (A-24) \]

where \( E_0^B \) stands for the lowest order ground state energy given by
\[ E^B_0 = \frac{N(N-1)}{2V} \psi(0) + \frac{1}{2} \sum_{k \neq 0} \left( E^B_B - \frac{k^2}{2m} - \frac{N}{V} \psi(k) \right), \quad (A-25) \]

and

\[ E^B_B = \frac{k}{2m} \sqrt{k^2 + \xi(k)} \quad (A-26) \]

gives the excitation energy in the lowest approximation.

The phonon-phonon interactions of the order of \( \sqrt{N} \) are given by (A-24).
Appendix B

Phonon-Phonon interactions and the excitation energy

In A, we have obtained the definite expression (A-24) of the phonon-phonon interactions by introducing the collective variables $\mathbf{p}_K$ and $\mathbf{v}_K$. In this section, let us derive a formula for the excitation spectrum in which the effects of the phonon-phonon interactions are taken into account. However, the traditional perturbation treatment of the interactions will produce a strongly divergent result, because the phonon-phonon interactions (A-24) involve the products of momenta $(p \cdot q)$. If we introduce a cutoff parameter to yield a finite result, the result will be fortuitous even if it is in good agreement with experiment for some value of the parameter, because the result is very sensitive to the magnitude of the parameter.

In order to overcome the difficulty mentioned above, we now adopt a slightly different method from the standard perturbation theory. The Schrödinger equation for the state of a single excitation $|\varphi_k\rangle$ is given by

$$\left(H - E_o - E_k^F\right)|\varphi_k\rangle = \delta E_R^F |\varphi_k\rangle$$

(B-1)

and

$$E_R^F = E_R^F + \delta E_R^F,$$

where $E_o$ is the eigenvalue for the exact ground state $|G\rangle$ of the total system and $E_k^F$ denotes the excitation energy of a single physical phonon. The Feynman excitation energy $E_k^F$ is defined by
Along the line of reasoning of the Feynman-Cohen theory (3), we assume that the single excitation state is approximately expressed by

$$|\Psi_R> = \rho^+_R|G> + \frac{1}{2} \sum \frac{C_{k-l,l'}}{l+l' +k} \rho^+_l \rho^+_{l'} |G>,$$

(B-3)

where we should note that the first and the second terms on the right-hand side of (B-3) are not orthogonal to each other. Introducing (B-3) into (B-1), we may obtain a set of equations:

$$\delta E_R \langle G| \rho^+_R \rho^+_{l'} |G> = \frac{1}{2} \sum \frac{C_{k-l,l'}}{l+l' +k} \langle G| \rho^+_R (H - E_F - E_R) \rho^+_{l'} |G>$$

$$+ \frac{1}{2} \sum \frac{C_{k-l,l'}}{l+l' +k} \langle G| \rho^+_R \rho^+_{l'} \rho^+_l |G> \delta E_R$$

(B-4)

and

$$\frac{1}{2} \sum \frac{C_{k-l,l'}}{l+l' +k} \langle G| \rho^+_{l'} (H - E_F - E_R) \rho^+_R \rho^+_l |G>$$

$$= - \langle G| \rho^+_{l'} (H - E_F - E_R) \rho^+_R |G>,$$

(B-5)

where use is made of the sum rule

$$\langle G| \rho^+_R (H - E_F - E_R) \rho^+_R |G> = 0.$$

The prescription of our method of calculation is to retain only the lowest nonvanishing matrix elements. Hence, the exact
structure factor $S(k)$ is approximated by $\wedge_R$ in the following way,

$$\langle G|p_{k_R}^+|G\rangle \approx \langle G|p_{k_R}^+|G\rangle = N \wedge_R,$$  \hspace{1cm} (B-7)

where the state $|G\rangle$ denotes the ground state of the free Hamiltonian $H_0$:

$$(H_0 - E_0^B)|G\rangle = 0.$$  \hspace{1cm} (B-8)

Because of the approximation adopted above, Feynman's excitation energy $E_F^F$ in (B-4) and (B-5) is replaced by Bogoliubov's one $E_B^B$, i.e.

$$E_F^F = \frac{k^2}{2m} \langle G|p_{k_R}^+|G\rangle = \frac{k^2}{2m} N \wedge_R.$$  \hspace{1cm} (B-9)

If we use the same prescription as above for the ground state energy, the energy $E_0^B$ which includes the effect of the phonon-phonon interactions should be replaced by the ground state energy $E_0^B$ in the nonvanishing lowest approximation. In the same way, we have

$$\langle G|p_{k_R}^+ p_{k_{R'}}^+ (H - E_0^B - E_{k_R}) p_{k_R}^+|G\rangle$$

$$\approx \langle G|p_{k_R}^+ p_{k_{R'}}^+ (H - E_0^B - E_{k_R}) p_{k_R}^+|G\rangle$$

$$= (E_{k_R}^B + E_{k_{R'}}^B - E_{k_R}) \wedge_{k_R} \wedge_{k_{R'}} (\delta_{l, l'} + \delta_{l', k_R - k}) N^2,$$

where the excitation energy $E_{k_R}$ remains as it is. Introducing (B-9) and (B-10) into (B-4) and (B-5), we may readily obtain
\[ \delta E_{kr} = -\sum_{l+K} \frac{1}{2N^3 \lambda_k \lambda_{l+K} \lambda_K} \left| \left\langle \psi \middle| \hat{p}_{l+K} \hat{p}_l (H - E_q^B - E_k^B) \hat{p}_k^+ \middle| \psi \right\rangle \right|^2 \]  \tag{B-11} 

and

\[ |\psi_{kr}\rangle = |\psi_{kr}\rangle - \frac{1}{2} \sum_{l+K} \frac{\left| \left\langle \psi \middle| \hat{p}_{l+K} \hat{p}_l (H - E_q^B - E_k^B) \hat{p}_k^+ \middle| \psi \right\rangle \right|}{N^2 \lambda_{l+K} \lambda_k \lambda_K (E_q^B + E_k^B - E_{kr})} \hat{p}_l^+ \hat{p}_{l+K}^+ |\psi\rangle. \tag{B-12} \]

In the course of derivation of (B-11) and (B-12), the second terms on the right hand sides of (B-4) and (B-5) have been neglected, since they can be regarded as higher order terms in comparison with other retained terms.

The calculation of the matrix elements in (B-11) and (B-12) should be carried out in the same spirit as the calculations of (B-9) and (B-10); that is, we take only the lowest nonvanishing value of the matrix element. Since the matrix elements in the numerators of (B-11) and (B-12) have odd density operators, it is required for us to take the phonon-phonon interaction \( H \) into account, and the physical ground state \( |\psi\rangle \) is written as

\[ |\psi\rangle \approx |\psi\rangle + \frac{1}{E_q^B - E_k^B} |H \rangle \tag{B-13} \]

By making use of (A-24) and (B-13), we have
\[ \langle G | \hat{P}_c \hat{P}_c G \rangle \]

\[ = -\frac{(N)^3}{8mN} \sum_{P, Q} \left( \frac{\lambda_{P+Q}}{\lambda_P \lambda_Q} \right) \frac{1}{E_P^B + E_Q^B + E_{P+Q}^B} \left\{ \langle G | B_2 B_{R-2} B_{P+Q} B_{P+Q}^t B_{P+Q}^t B_{P+Q}^t G \rangle + \langle G | B_2 B_{R-2} B_{P+Q} B_{P+Q}^t B_{P+Q}^t B_{P+Q}^t G \rangle \right\} \]

\[ = \frac{(N)^3}{2mN} \left\{ (k \cdot l) \lambda_{l-k} (1+\lambda_i l_i) \lambda_{l-k} (1+\lambda_i l_i) \right\} \]
By using (B-14) and (B-15), the straightforward calculation yields

\[
\langle G | P_{R-e} P_e (H - E^B_R - E^g_R) P^+_R | G \rangle
\]

\[
= \frac{(\text{IN})^3}{4m^2N^2} \lambda_R \left\{ \frac{(k^2 + l^2 + (k - l)^2)(kR - l)^2}{\lambda_R^2} (1 - \lambda_R)^2 - 2kR \lambda_R (kR - l)(\lambda_R - \lambda_R^2)^2 \right\}
\]

\[
\times \left( \lambda_R + (k - l)^2 \right) \lambda_R \lambda_R + k^2 l^2 \lambda_R - \lambda_R (kR - l)^2 \lambda_R \lambda_R (1 - \eta_R)
\]

(B-16)

Inserting (B-16) into (B-11), we have a fundamental formula for the excitation energy in the following form:

\[
E_R = E^g_R + \delta E_R = E^B_R (1 - \eta_R)
\]

(B-17)

where \( \eta_R \) indicates the ratio of the correction due to the phonon-phonon interaction to the lowest Bogoliubov excitation energy \( E^B_R \) and is determined by the equation

\[
\eta_R = \frac{\lambda_R^3}{8Nk^2} \sum_{l \neq R} \frac{(k^2 + l^2 + (k - l)^2)^2}{\lambda_R^2} \left( \frac{(kR - l)^2}{\lambda_R^2} (1 - \lambda_R)^2 - 2kR \lambda_R (kR - l)(\lambda_R - \lambda_R^2)^2 \right)
\]

\[
\times \left( \lambda_R + (k - l)^2 \right) \lambda_R \lambda_R + k^2 l^2 \lambda_R - \lambda_R (kR - l)^2 \lambda_R \lambda_R (1 - \eta_R)
\]

(B-18)

It should be noted here that the correction term \( \eta_R \) in (B-18) vanishes for the case of the non-interacting system (\( \lambda_R = 1 \)) as they should, and that the integral in (B-18) does strongly converge irrespective of the form of the potential function between helium atoms in contrast to that based on the standard perturbation theory. By virtue of this reason, we can use a simple square-well potential (see Fig. B-1)
as an idealization of the realistic potential, where $V_a$ indicates the height of the repulsive potential and $V_b$ denotes the depth of the attractive potential. The parameters $a$ and $b$ represent the range of the repulsive potential and that of the attractive one, respectively. In the case of the realistic potential, however, the repulsive core is not soft like (B-19), but is regarded as a hard core. In this respect, the potential (B-19) seems to be very far from reality. For the hard sphere potential, however, the Fourier transform of the potential function produces divergence, because the plane wave does not vanish in the hard sphere region. In reality, the amplitude of the wave function vanishes in the region of the hard sphere potential, and the product of the hard sphere potential and the wave function remains to be finite. So long as one uses the Fourier transform, therefore, use of the hard sphere potential is not adequate and it should be replaced by a finite effective potential. From the arguments mentioned above, we should realize that the height $V_a$ of the repulsive potential in (B-19) does not literally represent the real
height of the repulsive potential, but gives the effective magnitude of the hard sphere interaction.

The Fourier transform of the potential (B-19) is given by

\[ \mathcal{V}(k) = \frac{4}{3} \pi \alpha^3 \mathcal{V}_b (n+1)(1-\gamma) H(k) , \]

\[ \gamma = \frac{1}{n+1} \left( \frac{b}{a} \right)^3 , \quad n = \frac{V_a}{V_b} \]

and

\[ H(k) = \frac{3}{1-\gamma} \left\lbrace \frac{j_1(ka)}{ka} - \frac{j_1(kb)}{kb} \right\rbrace \]

where \( j_1 \) is the first order spherical Bessel function. The function \( c(k) \) defined by (A-21) is written as

\[ C^2(k) = C^2 H(k) \]

and

\[ C^2 = \frac{16}{3} \pi \frac{N}{V} \mathcal{V}_b \frac{m_0^3}{k^2} (n+1)(1-\gamma) \]

We now fix the mean density \( N/V \) and the constant \( c \) with the observed values

\[ \frac{N}{V} = 1/45.8 \, \text{Å}^{-3} \]

and

\[ c = \frac{2m_s}{h} = 2.99 \, \text{Å}^{-1} \]

where \( S = 2.37 \times 10^4 \, \text{cm/s} \) is the observed phonon velocity.

For the parameters \( a \) and \( b \), we set \( a = 2.8 \, \text{Å} \) and \( b = 4.4 \, \text{Å} \).
which are reasonable values as the ranges of the interaction potential between two helium atoms. The remaining parameter should be determined so that we have a reasonable value for the depth of the square-well attractive potential $V_b$ from (B-23) and (B-20). If we choose $\gamma = 0.60$ which corresponds to take $n = 5.5$, we have a reasonable value $V_b = 7.2 \times 10^{-16}$ erg.

By using the parameters chosen above, the equation (B-18) for $\eta_R$ is solved numerically and the solutions give the multi-branch excitation spectra shown in Fig. B-2.
Appendix C

Projection operator and the velocity operator

In A, we have introduced the projection operator $P(k)$ and the velocity operator to rewrite the original Hamiltonian (A-1) in terms of the collective variables. This appendix is devoted to the proof of the property of the projection operator, i.e. $P(k) = \sum_{k=1}^{N} P_{k,0}$ and the derivation of the second commutation relation of (A-6).

The projection operator $P(k)$ is given by

$$P(k) = \sum_{l} a_{l} \frac{1}{N} a_{l+K}^{\dagger} - \sum_{m=0} a_{l} \frac{1}{N} \rho_{m} \frac{1}{N} a_{2-m+K}^{\dagger} + \cdots \quad (C-1)$$

We transform each term of the right hand side of (C-1) into

$$\sum_{l} a_{l} \frac{1}{N} a_{l+K}^{\dagger} = \sum_{l} \frac{1}{N} a_{l} a_{l+K}^{\dagger} - \sum_{l} \frac{1}{N} a_{l} a_{l+K}^{\dagger} \quad (C-2)$$

$$\sum_{m=0} a_{l} \frac{1}{N} \rho_{m} \frac{1}{N} a_{2-m+K}^{\dagger} = \sum_{m=0} \frac{1}{N} \rho_{m} a_{l} a_{2-m+K}^{\dagger} + \sum_{m=0} \frac{1}{N} a_{l} a_{2-m+K}^{\dagger} \quad (C-3)$$

and so on. Combining the second terms on the right hand side of (C-2) and (C-3), we have

$$- \sum_{l} \frac{1}{N} a_{l} \frac{1}{N} a_{l+K}^{\dagger} - \sum_{m=0} \frac{1}{N} a_{l} \frac{1}{N} \rho_{m} \frac{1}{N} a_{2-m+K}^{\dagger}$$

$$= - \sum_{m=0} \frac{1}{N} a_{l} \frac{1}{N} \rho_{m} \frac{1}{N} a_{l-m+K}^{\dagger} \quad .$$
By repeating this procedure for all terms of (C-1), we rewrite (C-1) in the following form:

\[
P(R) = \sum_\mathcal{Q} \frac{1}{\mathcal{N}} a_\mathcal{Q} a^\dagger_{\mathcal{Q} + \mathcal{R}} - \sum_{m=0}^{\mathcal{N}} \frac{1}{\mathcal{N}} P_m \left\{ \sum_\mathcal{Q} \frac{1}{\mathcal{N}} a^\dagger_\mathcal{Q} a_{\mathcal{Q} - m + \mathcal{R}} - \sum_{p=0}^{\mathcal{N}} \frac{1}{\mathcal{N}} a_\mathcal{P} a^\dagger_{\mathcal{P} - m + \mathcal{R}} \right\} + \cdots \]

\[- \frac{1}{\mathcal{N}} \sum_{m=0}^{\mathcal{N}} \left\{ \sum_\mathcal{Q} \frac{1}{\mathcal{N}} a^\dagger_\mathcal{Q} a_{\mathcal{Q} - m + \mathcal{R}} - \sum_{p=0}^{\mathcal{N}} \frac{1}{\mathcal{N}} a_\mathcal{P} a^\dagger_{\mathcal{P} - m + \mathcal{R}} \right\} \]  

(C-4)

Using the equation (C-1) in (C-4), we obtain an integral equation

\[
P(R) = \sum_\mathcal{Q} \frac{1}{\mathcal{N}} a_\mathcal{Q} a^\dagger_{\mathcal{Q} + \mathcal{R}} - \sum_{m=0}^{\mathcal{N}} \frac{1}{\mathcal{N}} P_m P(R-m) - \frac{1}{\mathcal{N}} \Delta P(R), \quad (C-5)
\]

where \(\Delta\) indicates \(\sum_\mathcal{Q}\). The integral equation for \(P(R)\) is rewritten in the following form

\[
P(R) = \frac{\Delta \delta_{R,0} + P_R}{\mathcal{N} + \Delta} - \frac{1}{\mathcal{N} + \Delta} \sum_{\mathcal{Q} + 0} P_\mathcal{Q} P(R-\mathcal{Q}) \quad (C-6)
\]

for the case of the Bose system. In the case of Fermi system, on the other hand, we get

\[
P(R) = \frac{\Delta \delta_{R,0} - P_R}{\mathcal{N} + \Delta} - \frac{1}{\mathcal{N} + \Delta} \sum_{\mathcal{Q} + 0} P_\mathcal{Q} P(R-\mathcal{Q}) \quad (C-7)
\]

where we should note the difference of the sign in the inhomogenous term in (C-6) and (C-7). Iterating the equation (C-6), we have

\[
P(R) = \frac{\Delta \delta_{R,0} + P_R}{\mathcal{N} + \Delta} - \frac{1}{\mathcal{N} + \Delta} \sum_{\mathcal{Q} + 0} P_\mathcal{Q} \left( \Delta \delta_{R-\mathcal{Q},0} + P_{R-\mathcal{Q}} \right) + \frac{1}{(\mathcal{N} + \Delta)^2} \sum_{\mathcal{Q} + 0} P_\mathcal{Q} P_{\mathcal{Q}} \left( \delta_{R-\mathcal{Q},0} + P_{R-\mathcal{Q}-\mathcal{M}} \right) + \cdots \quad (C-8)
\]
In the case of $k=0$, the equation (c-8) becomes

$$
P(0) = 1 - \frac{1}{N+\Delta} \sum_{\ell=0} P_{\ell} P_{-\ell} + \frac{1}{(N+\Delta)^2} \sum_{\ell=0, m=0}^{m} P_{\ell} P_{m} (\delta_{\ell m} \delta_{m,0} + P_{m-m})$$

$$= 1 - \frac{1}{(N+\Delta)^2} \sum_{\ell=0} P_{\ell} P_{-\ell} + \frac{1}{(N+\Delta)^2} \sum_{\ell=0, m=0} P_{\ell} P_{m} P_{m-m}$$

$$= 1 . \quad (c-9)$$

In the case of $k \neq 0$, on the other hand, one can see that

$$
P(k) = \frac{P_k}{N+\Delta} - \frac{1}{(N+\Delta)^2} \sum_{\ell=0} P_{\ell} (\delta_{k-k,0} + P_{k-k})$$

$$+ \frac{1}{(N+\Delta)^3} \sum_{\ell=0, m=0} P_{\ell} P_{m} (\delta_{k-k-m,0} + P_{k-k-m})$$

$$= \frac{P_k}{N+\Delta} - \frac{P_k}{N+\Delta} - \frac{1}{(N+\Delta)^2} \sum_{\ell=0} P_{\ell} P_{k-k}$$

$$+ \frac{1}{(N+\Delta)^3} \sum_{\ell=0} P_{\ell} P_{k-k}$$

$$= 0 . \quad (c-10)$$

Hence we can conclude that

$$
P(k) = 1 \delta_{k,0} \quad (c-11)$$

for the case of Bose system.
On the other hand, we cannot derive the relation (C-11) for the case of the Fermi system, because of the difference of the sign in front of $p_k$ in the first term on the right hand side of (c-7).

The proof of the commutation relation $[v^{(1)}_k, v^{(2)}_k] = 0$ is achieved by using the property of the projection operator mentioned above. If we introduce the integral equations defined by

$$R_k = \frac{1}{N} q_k^+ - \sum_{\ell \neq 0} \frac{1}{N} p_\ell R_{k-\ell}$$  \hspace{1cm} (C-12)

and by

$$S_k = \frac{1}{N} \delta_{k,0} - \sum_{\ell \neq 0} \frac{1}{N} p_\ell S_{k-\ell}$$ \hspace{1cm} (C-13)

the velocity operator given by (A-5) is rewritten as

$$v_k = \sum_m R_{m-k} m a_m + \frac{1}{2} \sum_m S_{R-m} m a_m.$$ \hspace{1cm} (C-14)

First we shall show that $R_k$ commutes exactly with $q_\ell$. We can see from (c-12) that the commutation relation of these operators is readily given by

$$[q_{\ell}, R_k] = \frac{1}{N} \delta_{\ell,k} - \frac{1}{N} q_{\ell} \left[ \frac{1}{N} q_k^+ - \sum_{\ell \neq 0} \frac{1}{N} p_\ell R_{k-\ell} \right]$$

$$- \frac{1}{N} \sum_{\ell \neq 0} q_{\ell-\ell} R_{k-\ell} - \sum_{\ell \neq 0} \frac{1}{N} p_\ell [q_{\ell}, R_{k-\ell}].$$ \hspace{1cm} (C-15)
By using (c-12), the second term on the right hand side of (c-15) becomes

\[-\frac{1}{N} q_p R_k\]

and the integral equation (C-15) is expressed as

\[[q_p, R_k] = \frac{1}{N} \delta_{p,R} - \sum \frac{1}{N} q_{p-l} R_{k-l} - \sum_{l \neq 0} \frac{1}{N} P_l [q_p, R_{k-l}] . \quad \text{(C-16)}\]

Noting (C-11), we find that the first term on the right hand side of (C-16) cancels out the second term, and hence we can conclude that

\[[q_p, R_k] = 0 . \quad \text{(C-17)}\]

We now turn our attention to the proof of the relation

\[k \times \nabla R = 0 . \]

By introducing two operators \(\vec{Q}_R\) and \(\vec{T}_R\) defined by

\[\vec{Q}_R = \sum (m-k) R_{m-k} \times m a_m \quad \text{(C-18)}\]

and by

\[\vec{T}_R = \sum (m+k) S_{k-m} \times m p_m \quad \text{(C-19)}\]

respectively, \(k \times \nabla R\) is expressed as

\[k \times \nabla R = -\vec{Q}_R + \frac{1}{2} \vec{T}_R . \quad \text{(C-20)}\]
From (C-12), $\vec{Q}_R$ is rewritten as

\[ \vec{Q}_R = \sum_{m} (m-k) \frac{1}{N} a^+_m x m a_m - \sum_{m} \sum_{k=0}^{l} \frac{1}{N} p \, R_{m-k-\ell} \times m a_m \]

\[ - \sum_{m} \sum_{k=0}^{l} \frac{1}{N} p \, (m-k-\ell) R_{m-k-\ell} \times m a_m , \quad (C-21) \]

where the restriction concerning the sum over momenta $l$ on the right hand side of (C-21) is taken off, because the contribution from $l=0$ vanishes. The second term on the right hand side of (C-21) is transformed into

\[ -\sum_{l,m,p} \frac{1}{N} p \, a^+_p a_0 R_{m-k-\ell} \times m a_m \]

\[ = -\sum_{l,m,p} \frac{1}{N} (p-l) a^+_p a_0 R_{l+m-k-p} \times m a_m \]

\[ = -\sum_{l,m,p} \frac{1}{N} p \, a^+_p a_0 R_{l+m-k-p} \times m a_m \]

\[ = -\sum_{m} \frac{1}{N} (m-k) \, a^+_m x m a_m , \quad (C-22) \]

where the last equality is due to (c-11), and the second one comes from the following relation

\[ \sum_{m,l} a^+_p R_{l+m-k-p} \, a_0 \times m a_m = 0 . \quad (C-23) \]

From (C-22) and (C-18), we can conclude that

\[ \vec{Q}_R = 0 . \quad (C-24) \]

In the same way, we find
\[ T_\mathbf{k} = 0 - \sum_{\mathbf{q} \leq \mathbf{k}} \frac{1}{N} P_\mathbf{q} T_{\mathbf{k} + \mathbf{q}} \]  
\hspace{1cm} \text{ (C-25)}

and hence

\[ T_\mathbf{k} = 0 \]  
\hspace{1cm} \text{ (C-26)}

With the aid of (C-24) and (C-26), one can conclude that

\[ \mathbf{k} \times V^R_\mathbf{k} = 0 \]  
\hspace{1cm} \text{ (C-27)}

The commutation relation between the velocity operators is given by

\[
\begin{align*}
\{ V^{(i)}_\mathbf{k}, V^{(j)}_\mathbf{k}' \} &= -\frac{1}{N^2} \sum_{\mathbf{P}} P^{\mathbf{P} - \mathbf{k} - \mathbf{k}'} \left( P^{(i)}_\mathbf{P} V^{(j)}_\mathbf{P} - P^{(j)}_\mathbf{P} V^{(i)}_\mathbf{P} \right) \\
&\quad - \frac{1}{N^2} \sum_{\mathbf{P}, \mathbf{Q}} P^{\mathbf{P} - \mathbf{k} - \mathbf{Q}} \left[ V^{(i)}_\mathbf{P}, V^{(j)}_\mathbf{Q} \right],
\end{align*}
\]  
\hspace{1cm} \text{ (C-28)}

where the symbol \( \sum' \) indicates that the term with \( \mathbf{P} = \mathbf{k} \) and \( \mathbf{Q} = \mathbf{k}' \) at the same time should be omitted from the sum.

Noting (C-27), we find the second commutation relation in (A-6);

\[ \{ V^{(i)}_\mathbf{k}, V^{(j)}_\mathbf{k}' \} = 0 \]  
\hspace{1cm} \text{ (C-29)}

Closing this section, we should give the remarks that the relations (c-11), (c-27) and (c-29) are valid only in the case of the Bose system.
Acknowledgements
