# SIMPLEX MOVES ON ELEMENTARY SURFACES

SHIN SATOH

(Received May 22, 1998)

### 1. Introduction

In this paper, a surface in  $R^4 = \{(x_1, x_2, x_3, t) | x_1, x_2, x_3, t \in R\}$  means a closed (oriented or not and connected or not) PL 2-manifold embedded in  $R^4$  locally flatly. For two surfaces F and F' in  $R^4$ , the following conditions are mutually equivalent (cf. [3]).

(1) F is ambient isotopic to F'.

(2) F is related with F' by a sequence of simplex moves on surfaces in  $\mathbb{R}^4$ .

On the other hand, it is usual to describe a surface in  $R^4$  by use of a motion picture method [1]; taking the *t*-coordinate as a height function, we consider a surface to be a one-parameter family of subsets in  $R^3$  that are the intersections of the surface and the parallel hyperplanes. A surface in  $R^4$  is said to be elementary if all of its critical points are elementary (that is, minimal points, maximal points, and saddle points).

Let  $\varphi_{\theta} : \mathbb{R}^4 \longrightarrow \mathbb{R}^4$  be a rotation about the  $x_1 x_2$ -plane by an angle  $\theta$ . If p is an elementary (resp. non-elementary) critical point of a surface F, then  $\varphi_{\theta}(p)$  is also an elementary (resp. non-elementary) critical point of  $\varphi_{\theta}(F)$  for a sufficiently small positive angle  $\theta$ . In particular, if F is elementary, then  $\varphi_{\theta}(F)$  is also elementary.

The purpose of this paper is to prove the following theorem.

**Theorem 1.1.** Let F and F' in  $\mathbb{R}^4$  be two elementary surfaces. The following conditions are mutually equivalent.

- (1) F is ambient isotopic to F'.
- (2)  $\varphi_{\theta}(F)$  is related with  $\varphi_{\theta}(F')$  by a sequence of simplex moves on elementary surfaces in  $\mathbb{R}^4$  for a sufficiently small positive angle  $\theta$ .

In Section 2, we introduce the notion of a degree of a point of a surface in  $\mathbb{R}^4$ . We give a sufficient condition to decide which critical points are elementary (Lemma 2.3). Section 3 is devoted to examining how a 3-simplex move changes the degree of a point of a surface (Lemma 3.1). In Section 4, we define a  $\Lambda$ -move, which is a deformation to "pick up" a critical point and change it into some elementary critical points. This deformation was used in [2]. We show that a  $\Lambda$ -move is decomposed into some 3-simplex moves (Lemma 4.2). In Section 5, we prove Theorem 1.1.

Throughout this paper, we work in the piecewise linear category.

### 2. Critical Points

Let  $\pi : \mathbb{R}^4 \longrightarrow \mathbb{R}^3$  be the projection defined by  $\pi(x_1, x_2, x_3, t) = (x_1, x_2, x_3)$ . We use the notation t(p) for the t-coordinate of a point p in  $\mathbb{R}^4$ . We consider the following condition for a compact polyhedron P in  $\mathbb{R}^4$ :

(2.1) Any two vertices v and v' of P satisfy that  $\pi(v) \neq \pi(v')$  and  $t(v) \neq t(v')$ .

We notice that  $\varphi_{\theta}(P)$  satisfies the condition (2.1) for a sufficiently small positive angle  $\theta$ . In this section, we assume that a surface F in  $R^4$  satisfies (2.1).

For a subset A of  $R^3$  and a subset B of R, we denote the subset  $A \times B \subset R^3 \times R = R^4$  by AB. If B consists of one point t, we use the notation A[t] for  $A\{t\}$ .

The intersection  $F \cap R^3[t]$  is an ordinary cross-section if it is the empty set or a closed 1-manifold in  $R^3[t]$ . The intersection  $F \cap R^3[t]$  is an exceptional cross-section if it is not an ordinary cross-section.

If  $F \cap R^3[t]$  is an exceptional cross-section, then there is a unique point p that has no neighborhood in  $F \cap R^3[t]$  homeomorphic to an interval. Such a point p is called a *critical point* of F. We note that a critical point must be a vertex of F, that is, a 0-simplex of any triangulation of F.

In this paper, maximal points, minimal points, and saddle points are called *elementary critical points*, where a saddle point is the singular point illustrated in Figure 2.1. The points of F except critical points are called the *ordinary points*. We say that F is an *elementary surface* if all the critical points of F are elementary.

Figure 2.1

For any point p of F, the number of the edges in the 1-dimensional polyhedron  $F \cap R^3[t(p)]$  around p is even.

DEFINITION 2.2. The *degree* of p of F is the half number of such edges and denoted by d(p; F).

The degree d(p; F) is 0 (resp. 1) if and only if p is a maximal point or a minimal point (resp. an ordinary point) of F. If  $d(p; F) \ge 3$ , then p is a non-elementary critical point of F. In the case of d(p; F) = 2, p is not necessarily a saddle point of F.

**Lemma 2.3.** Let K be a triangulation of F which contains a vertex p. If the number of the edges in K around p is less than or equal to five, then p is an elementary critical point or an ordinary point.

Proof. Let  $|pv_1|, |pv_2|, \dots, |pv_n|$  be the 1-simplices in K such that the link Lk(p; F) = |Lk(p; K)| is  $|v_1v_2| \cup |v_2v_3| \cup \dots \cup |v_nv_{n+1}|$  ( $v_{n+1} = v_1$ ). Since 2d(p; F) is equal to the number

$$\#\{i|t(v_i) < t(p) < t(v_{i+1}) \text{ or } t(v_i) > t(p) > t(v_{i+1})\},$$

we have  $d(p; F) \leq 2$ . It suffices to consider the case of d(p; F) = 2.

We take a small cylindrical neighborhood N[a, b] of p in  $\mathbb{R}^4$ , where N is a convex linear 3-ball in  $\mathbb{R}^3$  and a < t(p) < b. Taking b - a to be a sufficiently small positive number, we may assume that the side  $(\partial N)[a, b]$  is disjoint from  $|pv_i|$   $(i = 1, \dots, n)$ . Let  $T_a(p; F)$  and  $T_b(p; F)$  be two tangles  $(N[a], F \cap N[a])$  and  $(N[b], F \cap N[b])$  respectively. Because of d(p; F) = 2,  $T_k(p; F)$  is a 2-string tangle (k = a, b). Each string of  $T_k(p; F)$  has one or two vertices corresponding to  $|pv_i| \cap N[k]$ , and in total two strings of  $T_k(p; F)$  have two or three vertices in intN[k] (k = a, b). Therefore we see that both  $T_a(p; F)$  and  $T_b(p; F)$  are trivial tangles.

We identify  $\partial T_a(p; F)$  with  $\partial T_b(p; F)^*$ , where  $T_b(p; F)^*$  is the mirror image of  $T_b(p; F)$ . Since  $T_a(p; F)$  and  $T_b(p; F)$  are trivial 2-string tangles and the union  $T_a(p; F) \cup_{\partial} T_b(p; F)^*$  is a trivial knot, there exists an isotopy  $\{h_s\}$   $(0 \le s \le 1)$  of N[a] = N[b] such that  $h_1(T_a(p; F))$  and  $h_1(T_b(p; F))$  have the forms  $N[t - \varepsilon]$  and  $N[t + \varepsilon]$  in Figure 2.1, respectively. This isotopy is extended to a level-preserving isotopy of  $R^4$ , and hence p is a saddle point of F. This completes the proof.

**REMARK 2.4.** We have the following equation:

$$\sum_{p\in F} \{d(p;F)-1\} = -\chi(F),$$

where  $\chi(F)$  is the Euler number of F. Since d(p; F) - 1 = 0 for any ordinary point p, the sum is finite.

#### 3. Simplex Move

Let P be a p-manifold in a q-manifold with p < q and  $\sigma^{p+1}$  be a (p+1)-simplex such that  $P \cap \sigma^{p+1} = P \cap \partial \sigma^{p+1}$  is the union of some p-faces of  $\sigma^{p+1}$ . Let P' be the

*p*-manifold  $cl(P \cup \partial \sigma^{p+1} - P \cap \partial \sigma^{p+1})$ . Then we say that P' is obtained from P by the (p+1)-simplex move associated with  $\sigma^{p+1}$ .

Suppose that F and F' are two surfaces in  $\mathbb{R}^4$  which satisfy (2.1)and that F' is obtained from F by a 3-simplex move associated with  $\sigma^3$ .

**Lemma 3.1.** For any point p of  $F \cap F'$ , we have

$$|d(p;F') - d(p;F)| \le 1$$

Figure 3.1

Proof. Let  $a_0, a_1, a_2$  and  $a_3$  be the vertices of  $\sigma^3$  with

 $t(a_0) < t(a_1) < t(a_2) < t(a_3)$ 

and  $\tau_i^2$  the 2-face of  $\sigma^3$  such that  $a_i * \tau_i^2 = \sigma^3$  (i = 0, 1, 2, 3). We say that the type of the 3-simplex move is (i), (ij), or (ijk) if  $F \cap \sigma^3 = \tau_i, \tau_i \cup \tau_j$ , or  $\tau_i \cup \tau_j \cup \tau_k$  for distinct  $i, j, k \in \{0, 1, 2, 3\}$  respectively; see Figure 3.1. In the figure, the black faces (resp. the white faces) indicate  $F \cap \sigma^3$  (resp.  $F' \cap \sigma^3$ ).

Suppose that the type of the 3-simplex move is (0); namely,  $F \cap \sigma^3$  consists of  $\tau_0^2 = |a_1 a_2 a_3|$ . If p is any point of  $F \cap F'$  except  $a_1, a_2$  and  $a_3$ , then it is obvious that d(p; F') - d(p; F) = 0. Consider the case  $p = a_1$ . Since  $Lk(a_1; F')$  is obtained from  $Lk(a_1; F)$  by replacing  $|a_2 a_3|$  with  $|a_2 a_0| \cup |a_0 a_3|$ , the difference  $d(a_1; F') - d(a_1; F)$  is +1. Similarly, if  $p = a_2$  or  $a_3$ , we have d(p; F') - d(p; F) = 0. Note that  $a_0$  is not in F but is in F' as a minimal point of F'.

The other types are similarly examined as shown in Table 3.1. In the table, the notation  $\times$  means that the difference  $d(a_i; F') - d(a_i; F)$  has no sense because  $a_i$  is not in both of F and F'. This completes the proof.

type	(0)	(1)	(2)	(3)
$\boxed{d(a_0;F')-d(a_0;F)}$	×	0	0	0
$d(a_1;F') - d(a_1;F)$	+1	×	0	0
$d(a_2;F') - d(a_2;F)$	0	0	×	+1

$d(a_3;F') - d(a_3;F)$	×	0	0	0

#### Table 3.1

In the case of d(p; F') - d(p; F) = 0 in Lemma 3.1, we have the following.

**Lemma 3.2.** Let p be a point of  $F \cap F'$ . If p is an elementary critical point (resp. an ordinary point) of F and d(p;F) - d(p;F') = 0, then p is also an elementary critical point (resp. an ordinary point) of F'.

Proof. If p is a maximal point or a minimal point, then d(p; F) = d(p; F') = 0and hence p is a maximal point or a minimal point of F'. If p is an ordinary point of F, then d(p; F) = d(p; F') = 1 and hence p is an ordinary point of F'.

Suppose that p is a saddle point of F. We use the notations in the proof of Lemma 2.3. Let  $D_k$  be  $\sigma^3 \cap N[k]$  (k = a, b). If  $D_k = \phi$ , then  $T_k(p; F) = T_k(p; F')$ . If  $D_k \neq \phi$ , then  $D_k$  is a 2-disk. In this case, we see that  $T_k(p; F)$  and  $T_k(p; F')$  are ambient isotopic and that  $T_k(p; F')$  is a trivial tangle; see Figure 3.2. Hence p is a saddle point of F'. This completes the proof.

Figure 3.2

Two p-manifolds P and P' in a q-manifold Q with p < q are related by a sequence of simplex moves on p-manifolds in Q if there exists a sequence of p-manifolds in Q

$$P = P_1 \longrightarrow P_2 \longrightarrow \cdots \longrightarrow P_n = P'$$

such that  $P_{i+1}$  is obtained from  $P_i$  by a (p+1)-simplex move  $(i = 1, 2, \dots, n-1)$ . Two elementary surfaces F and F' in  $R^4$  are related by a sequence of simplex moves on elementary surfaces in  $R^4$  if there exists a sequence of elementary surfaces in  $R^4$ 

 $F = F_1 \longrightarrow F_2 \longrightarrow \cdots \longrightarrow F_n = F'$ 

such that  $F_{i+1}$  is obtained from  $F_i$  by a 3-simplex move  $(i = 1, 2, \dots, n-1)$ . Kamada, Kawauchi and Matumoto proved the following theorem in [3].

**Theorem 3.3.** Let P and P' be two p-manifolds in a q-manifold Q with p < q. The following conditions are mutually equivalent.

- (1) P is ambient isotopic to P'.
- (2) P is related with P' by a sequence of simplex moves on p-manifolds in Q.

If two elementary surfaces F and F' in  $\mathbb{R}^4$  are ambient isotopic, then there exists a sequence of 3-simplex moves on surfaces in  $\mathbb{R}^4$ 

$$F = F_1 \longrightarrow F_2 \longrightarrow \cdots \longrightarrow F_n = F'$$

by Theorem 3.3. However  $F_i$  does not necessarily satisfy (2.1) ( $i = 2, \dots, n-1$ ). Taking a sufficiently small positive angle  $\theta$ , we obtain a sequence of 3-simplex moves

$$\varphi_{\theta}(F) = \varphi_{\theta}(F_1) \longrightarrow \varphi_{\theta}(F_2) \longrightarrow \cdots \longrightarrow \varphi_{\theta}(F_n) = \varphi_{\theta}(F').$$

such that  $\varphi_{\theta}(F_i)$  satisfies (2.1); nevertheless  $\varphi_{\theta}(F_i)$  is not necessarily an elementary surface. Our theorem (Theorem 1.1) asserts that we can replace the intermediate surfaces of the above sequence with another ones which are all elementary.

#### 4. $\Lambda$ -move

For a point p of a surface F which satisfies (2.1), we take a sufficiently small cylindrical neighborhood N[a, b] of p in  $\mathbb{R}^4$  such that the bottom N[a] and the top N[b] are disjoint from F, where N is a convex linear 3-ball in  $\mathbb{R}^3$  (this is different from the one defined in the proof of Lemma 2.3). We remove the 2-ball  $F \cap N[a, b]$  and replace it by a cone  $\hat{p} * \{F \cap (\partial N)[a, b]\}$  so that we obtain a new surface F', where  $\hat{p}$  is in intN[b]. We say that F' is obtained from F by a  $\Lambda$ -move at p, and denote F' by  $F_p$ .

In comparison between the vertices of F and  $F_p$ , p is not in  $F_p$  and  $v_1, \dots, v_n$ and  $\hat{p}$  are in  $F_p$ , where  $v_i$   $(i = 1, \dots, n)$  are the vertices of the polygonal curve  $F \cap (\partial N)[a, b]$ . Taking an appropriate 3-ball N, we make  $F_p$  satisfy (2.1). Throughout this paper we may assume that, if F satisfies (2.1), then  $F_p$  also satisfies (2.1).

We see that  $\hat{p}$  is a maximal point of  $F_p$  and that  $v_i$  is an elementary critical point or an ordinary point of  $F_p$  by Lemma 2.3. Hence we have the following (cf. [2]).

**Lemma 4.1.** If all the critical points of F except p are elementary, then  $F_p$  is an elementary surface. In particular, if F is elementary, then  $F_p$  is also elementary.

**Lemma 4.2.** If F is elementary, then F and  $F_p$  are related by a sequence of simplex moves on elementary surfaces.

Proof. Let  $\ell(p; F)$  be a polygonal curve  $F \cap (\partial N)[a, b]$  in  $(\partial N)[a, b]$ . By Theorem 3.3, if p is a maximal point, an ordinary point, or a saddle point, then there exists a sequence of 2-simplex moves on polygonal curves in  $int(\partial N)[a, b]$ 

$$\ell(p;F) = \ell_1 \longrightarrow \ell_2 \longrightarrow \cdots \longrightarrow \ell_n = \partial \tau^2$$

such that

- (1)  $\tau^2$  is a 2-simplex in  $int(\partial N)[a, t(p)]$ ,
- (2)  $\ell_{i+1}$  is obtained from  $\ell_i$  by a 2-simplex move associated with  $\tau_i^2$   $(i = 1, 2, \dots, n-1)$ ,

(3)  $\{p\} \cup \ell_i \text{ satisfies } (2.1) \ (i = 1, 2, \dots, n), \text{ and }$ 

(4)  $\#\{\ell_1 \cap (\partial N)[t(p)]\} \ge \#\{\ell_2 \cap (\partial N)[t(p)]\} \ge \cdots \ge \#\{\ell_n \cap (\partial N)[t(p)]\} = 0.$ 

Note that  $\sharp\{\ell_i \cap (\partial N)[t(p)]\}\$  is equal to  $2d(p; F_i)$  and hence  $\sharp\{\ell_1 \cap (\partial N)[t(p)]\}\$  is equal to 0, 2, or 4. If p is a minimal point, we replace " $int(\partial N)[a, t(p)]$ " in (1) by " $int(\partial N)[t(p), b]$ ". Then we have a sequence of surfaces in  $\mathbb{R}^4$ 

$$F = F_1 \longrightarrow F_2 \longrightarrow \cdots \longrightarrow F_n$$
$$\longrightarrow (F_n)_p \longrightarrow \cdots \longrightarrow (F_2)_p \longrightarrow (F_1)_p = F_p$$

such that

- (5)  $F_{i+1}$  is obtained from  $F_i$  by a 3-simplex move associated with  $p * \rho_i^2$ , where  $\rho_i^2$  is a 2-simplex in  $R^4$   $(i = 1, 2, \dots, n-1)$ ,
- (6)  $F_i$  satisfies (2.1)  $(i = 2, \dots, n)$ , and
- (7)  $(p * \rho_i^2) \cap (\partial N)[a, b] = \tau_i^2 \ (i = 1, 2, \cdots, n-1).$

Using this sequence, we prove that F and  $F_n$ ,  $F_n$  and  $(F_n)_p$ ,  $(F_n)_p$  and  $F_p$  are related by a sequence of simplex moves on elementary surfaces, respectively.

First, p is an elementary critical point or an ordinary point of  $F_i$  by (4) and Lemma 3.2. Moreover, the new vertices of  $F_i$  generated by the 3-simplex move associated with  $p * \rho_{i-1}^2$  are elementary critical points or ordinary points of  $F_i$  by Lemma 2.3. Hence  $F_i$  is an elementary surface. It follows that F and  $F_n$  are related by a sequence of simplex moves on elementary surfaces.

Second, let  $F'_n$  be a surface obtained from  $F_n$  by the 3-simplex move associated with  $p * \tau^2$ . Then  $(F_n)_p$  is obtained from  $F'_n$  by the 3-simplex move associated with  $\hat{p} * \tau^2$ . We see that  $F'_n$  and  $(F_n)_p$  are elementary surfaces by Lemma 2.3, and hence  $F_n$  and  $(F_n)_p$  are related by a sequence of simplex moves on elementary surfaces.

Finally, we notice that  $(F_i)_p$  is an elementary surface by Lemma 4.1. We remove the 3-simplex  $p * \tau_i^2$  from  $p * \rho_i^2$  and replace it by the 3-simplex  $\hat{p} * \tau_i^2$  so that we obtain the 3-ball  $B_i^3$   $(i = 1, 2, \dots, n-1)$ . Then two elementary surfaces  $(F_{i+1})_p$  and  $(F_i)_p$ differ by  $B_i^3$ .

By assuming Lemma 4.3 which is stated below, we see that  $(F_{i+1})_p$  and  $(F_i)_p$  are related by a sequence of simplex moves on elementary surfaces. It follows that  $(F_n)_p$  and  $F_p$  are related by a sequence of simplex moves on elementary surfaces, and we have the conclusion.

Let  $a_0 * \rho^2 = |a_0a_1a_2a_3|$  be a 3-simplex in  $\mathbb{R}^4$  which satisfies (2.1). We take a 2-simplex  $\tau^2 = |b_1b_2b_3|$  in  $a_o * \rho^2$  which satisfies (2.1), where  $b_i$  is an interior point of  $|a_0a_i|$  and close to  $a_0$  (i = 1, 2, 3). Let  $b_0$  be a point in  $\mathbb{R}^4$  such that  $b_0$  is joinable with  $\tau^2$ ,  $\operatorname{cl}(a_0 * \rho^2 - a_0 * \tau^2) \cap (b_0 * \tau^2) = \tau^2$ , and  $t(b_0) > t(b_i)$  (i = 1, 2, 3). Let F and  $F_B$  be two elementary surfaces such that  $F_B$  is obtained from F by a 3-cellular

move associated with a 3-ball  $B^3 = (a_0 * \rho - a_0 * \tau^2) \cup (b_0 * \tau^2)$ . Suppose that  $F \cap B^3$  is a 2-ball which is  $T_1, T_2, T_3, T_{12}, T_{13}$  or  $T_{23}$ , where

$$\begin{array}{rcl} T_1 &=& (|a_0a_2a_3| - |a_0b_2b_3|) \cup |b_0b_2b_3| \cup |a_1a_2a_3|, \\ T_2 &=& (|a_0a_1a_3| - |a_0b_1b_3|) \cup |b_0b_1b_3| \cup |a_1a_2a_3|, \\ T_3 &=& (|a_0a_1a_2| - |a_0b_1b_2|) \cup |b_0b_1b_2| \cup |a_1a_2a_3|, \\ T_{12} &=& (|a_0a_2a_3| - |a_0b_2b_3|) \cup |b_0b_2b_3| \\ & \cup & (|a_0a_1a_3| - |a_0b_1b_3|) \cup |b_0b_1b_3| \cup |a_1a_2a_3|, \\ T_{13} &=& (|a_0a_2a_3| - |a_0b_2b_3|) \cup |b_0b_2b_3| \\ & \cup & (|a_0a_1a_2| - |a_0b_1b_2|) \cup |b_0b_1b_2| \cup |a_1a_2a_3|, \text{ and} \\ T_{23} &=& (|a_0a_1a_3| - |a_0b_1b_3|) \cup |b_0b_1b_3| \\ & \cup & (|a_0a_1a_2| - |a_0b_1b_2|) \cup |b_0b_1b_3| \\ & \cup & (|a_0a_1a_2| - |a_0b_1b_2|) \cup |b_0b_1b_3| \\ & \cup & (|a_0a_1a_2| - |a_0b_1b_2|) \cup |b_0b_1b_3| \\ \end{array}$$

**Lemma 4.3.** In the above situation, F and  $F_B$  are related by a sequence of simplex moves on elementary surfaces.

Proof. We may assume that  $t(b_1) < t(b_2) < t(b_3)$ . According to the levels of  $a_1$  and  $b_1$ ,  $a_2$  and  $b_2$ ,  $a_3$  and  $b_3$ , we have four cases;

 $\begin{array}{ll} (\text{i-1}) \ t(a_1) > t(b_1), t(a_2) > t(b_2), t(a_3) > t(b_3), \\ (\text{i-2}) \ t(a_1) < t(b_1), t(a_2) > t(b_2), t(a_3) > t(b_3), \\ (\text{i-3}) \ t(a_1) < t(b_1), t(a_2) < t(b_2), t(a_3) > t(b_3), \text{ and} \\ (\text{i-4}) \ t(a_1) < t(b_1), t(a_2) < t(b_2), t(a_3) < t(b_3). \end{array}$ 

According to the levels of  $a_1$ ,  $a_2$  and  $a_3$ , we have six cases;

(ii-1)  $t(a_1) < t(a_2) < t(a_3)$ , (ii-2)  $t(a_1) < t(a_3) < t(a_2)$ , (ii-3)  $t(a_2) < t(a_1) < t(a_3)$ , (ii-4)  $t(a_2) < t(a_3) < t(a_1)$ , (ii-5)  $t(a_3) < t(a_1) < t(a_2)$ , and (ii-6)  $t(a_3) < t(a_2) < t(a_1)$ .

If the levels of the vertices of  $B^3$  are of type (i- $\alpha$ ) and (ii- $\beta$ ), then say that  $B^3$  is of type ( $\alpha, \beta$ ), where  $\alpha \in \{1, 2, 3, 4\}$  and  $\beta \in \{1, 2, 3, 4, 5, 6\}$ . We notice that there exist no 3-balls  $B^3$  of types (2,3), (2,4), (2,5), (2,6), (3,2), (3,4), (3,5), and (3,6). For each type ( $\alpha, \beta$ ), there are six cases according to  $F \cap B^3 = T_1, T_2, T_3, T_{12}, T_{13}$  and  $T_{23}$ .

Case 1. Suppose that  $B^3$  is of type (1,1), (1,2), (1,3), (1,4), (1,5), (1,6), (2,1) or (2,2).

First, we consider the case that  $B^3$  is of type (1,1) and  $F \cap B^3$  is  $T_1$ . As the division of  $B^3$ , we take four 3-simplices  $\Delta_1^3, \Delta_2^3, \Delta_3^3, \Delta_4^3$ , where

$$\Delta_1^3 = |a_1 a_2 a_3 b_1|, \Delta_2^3 = |a_2 a_3 b_1 b_2|, \Delta_3^3 = |a_3 b_1 b_2 b_3|, \text{ and } \Delta_4^3 = |b_0 b_1 b_2 b_3|.$$

Then F and  $F_B$  are related by a sequence of simplex moves on surfaces which satisfy the condition (2.1);

$$F = F_1 \xrightarrow{\Delta_1} F_2 \xrightarrow{\Delta_2} F_3 \xrightarrow{\Delta_3} F_4 \xrightarrow{\Delta_4} F_5 = F_B,$$

see Figure 4.1. Then the difference of the degrees of the vertices of  $B^3$  is given in Table 4.1.

Figure 4.1

vertex	$a_1$	$a_2$	$a_3$	$b_0$	$b_1$	$b_2$	$b_3$
$d(*;F_2) - d(*;F_1)$	+1	0	0	0	×	0	0
$d(*;F_3) - d(*;F_2)$	0	-1	0	0	0	+1	0
$d(*;F_4) - d(*;F_3)$	0	0	0	0	0	0	0
$d(*;F_5) - d(*;F_4)$	0	0	0	0	0	0	0

Tab	le 4	ŀ.	1
Iuo.		••	

Since  $a_1$  is an elementary critical point or an ordinary point of  $F_5$ , we have  $d(a_1; F_1) \leq 1$ . If the vertex  $a_1$  is a maximal point or a minimal point of  $F_1$ , then  $a_1$  is an ordinary point of  $F_2, F_3, F_4$  and  $F_5$ . If  $a_1$  is an ordinary point of  $F_1$ , then  $a_1$  is a saddle point of  $F_2, F_3, F_4$  and  $F_5$  by Lemma 3.2.

Similarly, the vertices  $a_2, a_3, b_0, b_1, b_2$  and  $b_3$  are elementary critical points or ordinary points of  $F_2, F_3$ , and  $F_4$  (in particular,  $b_1$  is a minimal point). Hence the surfaces  $F_2, F_3$  and  $F_4$  are elementary surfaces, and F and  $F_B$  are related by simplex moves on elementary surfaces.

#### Table 4.2

In Case 1 generally, we use one of the following six kinds of order of simplex moves;

For each type in Case 1, we give an example of order such that F and  $F_B$  are related by a sequence of simplex moves on elementary surfaces; see Table 4.2.

Case 2. Suppose that  $B^3$  are of type (3,1), (3,3), (4,1), (4,2), (4,3), (4,4), (4,5) or (4,6).

As the division of  $B^3$ , we take four 3-simplices  $\Delta_4^3, \Delta_5^3, \Delta_6^3, \Delta_7^3$ , where

$$\Delta_5^3 = |a_1 a_2 a_3 b_3|, \Delta_6^3 = |a_1 a_2 b_2 b_3|, \text{ and } \Delta_7^3 = |a_1 b_1 b_2 b_3|.$$

We use one of the following four kinds of order of simplex moves;

$Q_1$ .	F = F	$f_1 \xrightarrow{\Delta_5} F_2$	$\xrightarrow{\Delta_6} F_3$	$\xrightarrow{\Delta_7} F_4$	$\xrightarrow{\Delta_4} F_5 =$	$F_B$ ,
$Q_2$ .	F = F	$1 \xrightarrow{\Delta_4} F_2$	$\xrightarrow{\Delta_5} F_3$	$\xrightarrow{\Delta_7} F_4$	$\xrightarrow{\Delta_6} F_5 =$	$F_B$ ,
$Q_3$ .	F = F	$f_1 \xrightarrow{\Delta_4} F_2$	$\xrightarrow{\Delta_7} F_3$	$\xrightarrow{\Delta_6} F_4$	$\xrightarrow{\Delta_5} F_5 =$	$F_B$ , and
$Q_4$ .	F = F	$1 \xrightarrow{\Delta_4} F_2$	$\xrightarrow{\Delta_5} F_3$	$\stackrel{\Delta_6}{\longrightarrow} F_4$	$\xrightarrow{\Delta_7} F_5 =$	$F_B$ .

For each type in Case 2, we give an example of order such that F and  $F_B$  are related by a sequence of simplex moves for elementary surfaces; see Table 4.3.

	.3
--	----

This completes the proof of Lemma 4.3.

For a surface F which satisfies (2.1), we denote the surface obtained by the  $\Lambda$ -moves at all the points of F with their degrees  $\geq 2$  by  $\hat{F}$ . Then  $\hat{F}$  is elementary (cf. Lemma 4.1). By Lemma 4.2, we have the following.

**Corollary 4.4.** For any elementary surface F in  $\mathbb{R}^4$ , F and  $\widehat{F}$  are related by a sequence of simplex moves on elementary surfaces.

### 5. Proof of Theorem 1.1

To prove Theorem 1.1, we prepare three more lemmas.

Let  $\sigma^3$  be a 3-simplex  $|a_0a_1a_2a_3|$  in  $\mathbb{R}^4$  which satisfies (2.1). We take a 2-simplex  $\rho_0^2 = |a_{01}a_{02}a_{03}|$  which satisfies (2.1), where  $a_{0i}$  (i = 1, 2, 3) is an interior point of

 $|a_0a_i|$  and close to  $a_0$  and the 3-simplex  $a_0 * \rho_0^2$  is similar to  $\sigma^3$ . Similarly we take 2-simplices  $\rho_1^2, \rho_2^2$  and  $\rho_3^2$  near  $a_1, a_2$  and  $a_3$  respectively.

Let F be an elementary surface and F' a surface in  $\mathbb{R}^4$  obtained from F by a 3simplex move associated with  $\sigma^3$ . For the set U of vertices of  $\sigma^3$  which are in  $F \cap F'$ , we take a 3-ball  $C^3 = \operatorname{cl}(\sigma^3 - \bigcup_{a_i \in U} a_i * \rho_i^2)$ . Let  $F_C$  be a surface obtained from F by the 3-cellular move associated with  $C^3$ . We notice that  $F_C$  satisfies (2.1). Then we have the following.

**Lemma 5.1.** (1)  $F_C$  is an elementary surface. (2) F and  $F_C$  are related by a sequence of simplex moves on elementary surfaces.

Proof. Let  $\tau_i^2$  be a 2-face of  $\sigma^3$  with  $a_i * \tau_i^2 = \sigma^3$  (i = 0, 1, 2, 3).

(1) If  $F \cap \sigma^3 = \tau_0^2 = |a_1 a_2 a_3|$ , then the new vertices  $a_0, a_{10}, a_{12}, a_{13}, a_{20}, a_{21}, a_{23}, a_{30}, a_{31}$  and  $a_{32}$  are generated in  $F_C$  by the 3-cellular move. The edges in  $F_C$  around  $a_{10}$  are  $|a_{10}a_0|, |a_{10}a_{12}|$ , and  $|a_{10}a_{13}|$ . Then  $a_0$  is an elementary critical point or an ordinary point of  $F_C$  by Lemma 2.3. We see that the rest of the vertices of  $F_C$  are also elementary critical points or ordinary points, and hence  $F_C$  is elementary. The other types are similarly examined.

(2) We may assume that  $t(a_0) < t(a_1) < t(a_2) < t(a_3)$ . We divide the proof into 14 cases according to  $F \cap \sigma^3$ .

Type (0). 
$$F \cap \sigma^3$$
 consists of  $\tau_0^2 = |a_1 a_2 a_3|$ .

As the division of  $C^3$ , we take seven 3-simplices:

We apply 3-simplex moves associated with these 3-simplices in this order to obtain a sequence of simplex moves on surfaces which satisfy (2.1)

$$F = F_1 \longrightarrow F_2 \longrightarrow \cdots \longrightarrow F_8 = F_C,$$

see Figure 5.1. We notice that the levels of the vertices of  $C^3$  are

$$\begin{array}{l} t(a_0) < \ t(a_{10}) < t(a_{12}) < t(a_{13}) < t(a_{20}) \\ < \ t(a_{21}) < t(a_{23}) < t(a_{30}) < t(a_{31}) < t(a_{32}). \end{array}$$

Then the difference of the degrees of these vertices is shown in Table 5.1.

Figure 5.1

vertex	$a_0$	$a_{10}$	$a_{12}$	$a_{13}$	$a_{20}$	$a_{21}$	a <sub>23</sub>	$a_{30}$	$a_{31}$	$a_{32}$

## Table 5.1

We see that  $F_2, \dots, F_6$  and  $F_7$  are elementary surfaces and that F and  $F_C$  are related by a sequence of simplex moves on elementary surfaces.

The other 13 cases are similarly examined. The following is an example of a division of  $C^3$  and an order of simplex moves for each case so that F and  $F_C$  are related by a sequence of simplex moves on elementary surfaces.

Type (2);  $F \cap \sigma^3 = \tau_2^2$ .

 $\begin{array}{l} |a_{03}a_{10}a_{2}a_{31}|, \ |a_{01}a_{02}a_{03}a_{10}|, \ |a_{02}a_{03}a_{10}a_{2}|, \ |a_{03}a_{30}a_{31}a_{32}|, \\ \\ |a_{03}a_{2}a_{31}a_{32}|, \ |a_{10}a_{12}a_{13}a_{31}|, \ |a_{10}a_{12}a_{2}a_{31}|. \end{array}$ 

Type (3);  $F \cap \sigma^3 = \tau_3^2$ .

Type (01);  $F \cap \sigma^3 = \tau_0^2 \cup \tau_1^2$ .

$ a_{02}a_{12}a_{23}a_{32} ,$	$ a_{02}a_{12}a_{21}a_{23} ,$	$ a_{02}a_{20}a_{21}a_{23} $	$,  a_{02}a_{10}a_{12}a_{32} ,$
	$ a_{10}a_{12}a_{13}a_{32} ,$	$ a_{10}a_{13}a_{31}a_{32} $	$,  a_{02}a_{10}a_{30}a_{32} ,$
	$ a_{10}a_{30}a_{31}a_{32} ,$	$ a_{01}a_{02}a_{10}a_{30} $	$ ,  a_{01}a_{02}a_{03}a_{30} .$

Type (02);  $F \cap \sigma^3 = \tau_0^2 \cup \tau_2^2$ .

$a_{03}a_{13}a_{23}a_{31} ,$	$ a_{03}a_{23}a_{31}a_{32} ,$	$ a_{03}a_{30}a_{31}a_{32} ,$	$ a_{03}a_{13}a_{20}a_{23} $	,
	$ a_{13}a_{20}a_{21}a_{23} ,$	$ a_{12}a_{13}a_{20}a_{21} ,$	$ a_{03}a_{10}a_{13}a_{20} $	,
	$ a_{10}a_{12}a_{13}a_{20} ,$	$ a_{01}a_{02}a_{03}a_{10} ,$	$ a_{02}a_{03}a_{10}a_{20} $	.

Type (03);  $F \cap \sigma^3 = \tau_0^2 \cup \tau_3^2$ .

Type (12);  $F \cap \sigma^3 = \tau_1^2 \cup \tau_2^2$ .

Type (13);  $F \cap \sigma^3 = \tau_1^2 \cup \tau_3^2$ .

Type (23);  $F \cap \sigma^3 = \tau_2^2 \cup \tau_3^2$ .

Type (012);  $F \cap \sigma^3 = \tau_0^2 \cup \tau_1^2 \cup \tau_2^2$ .

Type (013);  $F \cap \sigma^3 = \tau_0^2 \cup \tau_1^2 \cup \tau_3^2$ .

Type (023);  $F \cap \sigma^3 = \tau_0^2 \cup \tau_2^2 \cup \tau_3^2$ .

Type (123);  $F \cap \sigma^3 = \tau_1^2 \cup \tau_2^2 \cup \tau_3^2$ .

 $\begin{array}{l} |a_0a_{23}a_{30}a_{31}|, \; |a_{23}a_{30}a_{31}a_{32}|, \; |a_0a_{12}a_{20}a_{23}|, \; |a_{12}a_{20}a_{21}a_{23}|, \\ \\ |a_0a_{12}a_{23}a_{31}|, \; |a_0a_{10}a_{12}a_{31}|, \; |a_{10}a_{12}a_{13}a_{31}|. \end{array}$ 

This completes the proof.

Let F and F' be two surfaces in  $\mathbb{R}^4$  such that they satisfy (2.1) and that F' is obtained from F by a 3-simplex move associated with  $p * \rho^2$ , where p is a vertex of  $F \cap F'$  and  $\rho^2$  is a 2-simplex in F. Suppose that all the critical points of F and F' except p are elementary. Let  $F_p$  (resp.  $F'_p$ ) be a surface obtained from F (resp. F') by the  $\Lambda$ -move at p.

For the cylindrical neighborhood N[a, b] of p in  $\mathbb{R}^4$  and the point  $\hat{p} \in \operatorname{int} N[b]$ associated with the  $\Lambda$ -move at p, we take a 2-ball  $D^2 = (p * \rho^2) \cap (\partial N)[a, b]$  and a 3-ball  $B^3 = (p * \rho^2 - p * D^2) \cup (\hat{p} * D^2)$ . By Lemma 4.1,  $F_p$  and  $F'_p$  are elementary surfaces and differ by  $B^3$ .

**Lemma 5.2.**  $F_p$  and  $F'_p$  are related by a sequence of simplex moves on elementary surfaces.

Proof. Let  $\ell_p$  (resp.  $\ell'_p$ ) be a polygonal curve  $F \cap (\partial N)[a, b]$  (resp.  $F' \cap (\partial N)[a, b]$ ) which satisfies (2.1). Then  $\ell_p$  and  $\ell'_p$  differ by  $D^2$ . We take a division of  $D^2$  into 2simplices  $\tau_1^2, \tau_2^2, \cdots, \tau_{n-1}^2$  such that the 2-simplex moves associated with  $\tau_1^2, \tau_2^2, \cdots, \tau_{n-1}^2$  are applied to  $\ell_p$  in this order to obtain  $\ell'_p$ .

Let  $p * \rho_i^2$  be a 3-simplex with  $(p * \rho_i^2) \cap (\partial N)[a, b] = \tau_i^2$  and  $\rho_i^2 \subset \rho^2$   $(i = 1, 2, \dots, n-1)$ . Notice that  $p * \rho^2$  is divided into  $\{p * \rho_1^2, p * \rho_2^2, \dots, p * \rho_{n-1}^2\}$ . Let  $B_i^3$  be a 3-ball  $(p * \rho_i^2 - p * \tau_i^2) \cup (\hat{p} * \tau_i^2)$   $(i = 1, 2, \dots, n-1)$ . We may assume that  $B_i^3$  satisfies (2.1). Then there exists a sequence of cellular moves on surfaces

$$F_p = F_1 \longrightarrow F_2 \longrightarrow \cdots \longrightarrow F_n = F'_p$$

such that  $F_{i+1}$  is obtained from  $F_i$  by the 3-cellular move associated with  $B_i^3$  and that  $F_i$  satisfies (2.1). By Lemma 4.3, two surfaces  $F_i$  and  $F_{i+1}$  are related by a sequence of simplex moves on elementary surfaces. This completes the proof.

Suppose that F and F' are surfaces in  $R^4$  which satisfy (2.1) and that F' is obtained from F by a 3-simplex move associated with  $\sigma^3$ .

**Lemma 5.3.**  $\widehat{F}$  and  $\widehat{F'}$  are related by a sequence of simplex moves on elementary surfaces.

Proof. Let  $\sigma^3$  be  $|a_0a_1a_2a_3|$  with  $t(a_0) < t(a_1) < t(a_2) < t(a_3)$ . We use the notations in Lemma 5.1. For the 3-ball  $C^3$  obtained by cutting the corners off from  $\sigma^3$ , we have a sequence of surfaces

$$F \longrightarrow F_C \longrightarrow F'.$$

We note that F' is obtained from  $F_C$  by the composition of the 3-simplex moves associated with  $a_i * \rho_i^2$  ( $a_i \in U$ ); see Figure 5.2.

Let S be the set of vertices of F with their degrees  $\geq 2$  except the vertices of  $\sigma^3$ . We classify the vertices in U into four (possibly empty) sets:

$$\begin{split} U_{11} &= \{ v | d(v; F) \leq 1, d(v; F') \leq 1 \}, \\ U_{12} &= \{ v | d(v; F) = 1, d(v; F') = 2 \}, \end{split}$$

Figure 5.2

 $\begin{array}{l} U_{21}=\{v|d(v;F)=2,d(v;F')=1\}, \text{ and }\\ U_{22}=\{v|d(v;F)\geq 2,d(v;F')\geq 2\}. \end{array}$ 

Then we obtain a sequence of surfaces between  $\widehat{F}$  and  $\widehat{F'}$ 

 $\widehat{F} = F_1 \longrightarrow F_2 \longrightarrow F_3 \longrightarrow F_4 \longrightarrow F_5 = \widehat{F'}$ 

such that

- (1)  $\widehat{F} = F_1$  is obtained from F by the composition of the  $\Lambda$ -moves at the vertices in  $S \cup U_{21} \cup U_{22}$ ,
- (2)  $F_2$  is obtained from  $F_C$  by the composition of the  $\Lambda$ -moves at the vertices in  $S \cup U_{21} \cup U_{22}$ ,
- (3)  $F_3$  is obtained from  $F_C$  by the composition of the  $\Lambda$ -moves at the vertices in  $S \cup U_{12} \cup U_{21} \cup U_{22}$ ,
- (4)  $F_4$  is obtained from F' by the composition of the  $\Lambda$ -moves at the vertices in  $S \cup U_{12} \cup U_{21} \cup U_{22}$ , and
- (5)  $F_5 = \widehat{F'}$  is obtained from F' by the composition of the  $\Lambda$ -moves at the vertices in  $S \cup U_{12} \cup U_{22}$ ; see Figure 5.3.

We notice that  $F_2, F_3$ , and  $F_4$  are elementary surfaces by Lemma 4.1. Then we have the following.

Figure 5.3

- (6) Since  $F_2$  is obtained from  $F_1$  by the 3-cellular move associated with  $C^3$ , two surfaces  $F_1$  and  $F_2$  are related by a sequence of simplex moves on elementary surfaces by Lemma 5.1(2).
- (7) Since  $F_3$  is obtained from  $F_2$  by the composition of the  $\Lambda$ -moves at the ordinary points in  $U_{12}$ , two surfaces  $F_2$  and  $F_3$  are related by a sequence of simplex moves on elementary surfaces by Lemma 4.2.
- (8) Since F<sub>4</sub> is obtained from F<sub>3</sub> by the composition of the 3-simplex moves associated with a<sub>i</sub> \* ρ<sub>i</sub><sup>2</sup> (a<sub>i</sub> ∈ U<sub>11</sub>) and the 3-cellular moves associated with the 3-balls constructed by picking the vertex a<sub>i</sub> of a<sub>i</sub> \* ρ<sub>i</sub><sup>2</sup> (a<sub>i</sub> ∈ U<sub>12</sub> ∪ U<sub>21</sub> ∪ U<sub>22</sub>), two surfaces F<sub>3</sub> and F<sub>4</sub> are related by a sequence of simplex moves on elementary surfaces by Lemma 5.2.
- (9) Since  $F_5$  is obtained from  $F_4$  by the composition of the inverse  $\Lambda$ -moves at the ordinary points in  $U_{21}$ , two surfaces  $F_4$  and  $F_5$  are related by a sequence of simplex moves on elementary surfaces by Lemma 4.2.

Therefore  $\widehat{F}$  and  $\widehat{F'}$  are related by a sequence of simplex moves on elementary surfaces and we have the conclusion.

We are ready to prove Theorem 1.1.

Proof of Theorem 1.1. It is well-known that  $(2) \Rightarrow (1)$  (cf. [4]). We may prove that  $(1) \Rightarrow (2)$ . Let F and F' be two elementary surfaces in  $\mathbb{R}^4$  which are ambient isotopic. By Theorem 3.3, there exists a sequence of simplex moves on surfaces in  $\mathbb{R}^4$ between F and F'. Rotating the surfaces and the 3-simplices in this sequence slightly, we obtain a sequence of simplex moves on surfaces in  $\mathbb{R}^4$  which satisfy (2.1)

$$\varphi_{\theta}(F) = F_1 \longrightarrow F_2 \longrightarrow \cdots \longrightarrow F_n = \varphi_{\theta}(F').$$

Deforming the surfaces in this sequence by  $\Lambda$ -moves at all the points with their degrees  $\geq$  2, we have a sequence of elementary surfaces

$$\varphi_{\theta}(F) = F_1 \longrightarrow \widehat{F_1} \longrightarrow \widehat{F_2} \longrightarrow \cdots \longrightarrow \widehat{F_n} \longrightarrow F_n = \varphi_{\theta}(F').$$

Then  $F_1$  and  $\widehat{F_1}$ ,  $\widehat{F_n}$  and  $F_n$  are related by a sequence of simplex moves on elementary surfaces by Corollary 4.4, respectively. Moreover,  $\widehat{F_i}$  and  $\widehat{F_{i+1}}$  are also related by a sequence of simplex moves on elementary surfaces by Lemma 5.3 ( $i = 1, 2, \dots, n-1$ ). Hence we obtain a required sequence of simplex moves on elementary surfaces between  $\varphi_{\theta}(F)$  and  $\varphi_{\theta}(F')$ .
