Abstract

Non-perturbative behavior of QCD appears as hadrons and their interactions. The mass, decay width and transition form factor of a nucleon resonance provide us basic and fundamental information to understand low energy QCD. Resonance parameters are extracted from amplitudes of $\pi N$ scattering, meson-photoproduction and electroproduction. The purpose of this work is to extract resonance parameters such as mass, width and electromagnetic transition form factors from the the $\pi N - \pi N$ and $\gamma^* N - \pi N$ amplitudes by analytic continuation. Meson-production reactions are dominated by final states of $\pi N$, $\eta N$ and $\pi\pi N$ in the energy region above 1.3 GeV. We have developed the dynamical reaction model which includes $\pi N$, $\eta N$ and also unstable particle channels $\sigma N$, $\rho N$ and $\pi\Delta$ coupled with $\pi\pi N$, but no analytic continuation method has been applied to such a dynamical model with unstable particle channels. In this work we develop an method of analytic continuation for the amplitude including those unstable channel. We apply the method for the scattering amplitude from the dynamical reaction model and extract mass, width and the electromagnetic $N - N^*$ transition form factors.

I. INTRODUCTION

Spectrum of the excited baryons and their properties provide us important and fundamental information to understand strong interactions. A clear understanding of the spectrum and decay scheme of excited baryons will reveal the role of confinement and chiral symmetry in the non-perturbative QCD.

Most of information about the mass, width and transition form factor of baryon resonances have been extracted from partial wave analyses of $\pi N$ scattering data[1] and sometimes the transition amplitudes to inelastic channels such as $\pi N \to \eta N$ [2] or $\pi N \to \pi\pi N$ [3, 4]. In addition there is information available from photo- and electroproduction of N* resonances. Recently, such data with high precision have been accumulated at Jefferson Laboratory, MIT-Bates, LEGS of Brookhaven National Laboratory, MAMI of Mainz, ELSA of Bonn, GRAAL of Grenoble, and LEPS of SPring-8. These data on the electromagnetic production of $\pi$, $\eta$, $K$, $\omega$, $\phi$ and $2\pi$ final states provide a opportunity to investigate the properties of excited baryons, as reviewed in Ref.[5].

Here, we briefly recall how resonances are defined in relation to S-matrix theory. By analytic continuation, a scattering amplitude can be defined on the complex energy plane. Its analytical structure is well studied[6–10] for the non-relativistic two-body scattering. For the single-channel case, the scattering amplitude is a single-valued function of momentum $p$ on the complex momentum p-plane, but it is a double-valued function of energy $E$ on the complex energy E-plane because of the quadratic relation $p = \sqrt{2mE}e^{i\phi_E/2}$. Therefore the complex E-plane is composed of two Riemann sheets. The physical (p) sheet is defined by specifying the range of phase $0 \leq \phi_E \leq 2\pi$, and the unphysical (u) sheet by $2\pi \leq \phi_E \leq 4\pi$. As illustrated in Fig. 1, the shaded area with Im $p > 0$ of the upper part of Fig. 1(a) corresponds to the physical E-sheet shown in Fig. 1(b). Similarly, the unphysical E-sheet shown in Fig. 1(c) corresponds to the Im $p < 0$ area in the lower part of Fig. 1(a). On the physical sheet, the only possible singularities are on the real E-axis: the bound state poles (solid square in Fig. 1(b)) below the threshold energy $E_{th}$ and the unitary cut from $E_{th}$ to infinity. On the unphysical sheet, a pole (solid circle in Fig. 1(c)) on the lower half plane and Re $E_{pole} > E_{th}$ corresponds to a resonance. From unitarity and analyticity of S-matrix, each resonance pole has an accompanied pole, called conjugate pole, which exists on the upper half of the unphysical sheet. A resonance pole
FIG. 1: The complex momentum $p$-plane ((a)) and its corresponding complex energy $E$-plane which has a physical sheet ((b)) and unphysical sheet ((c)). Their correspondence is indicated by the same number. Solid squares (circles) represent the bound state (resonance) poles.

is due to the mechanism: an unstable system is formed and decay subsequently during the collision. The mathematical details of this interpretation can be found in textbooks, such as in chapter 8 of Goldberger and Watson[11].

For multi-channel case, the analytic structure of the scattering amplitude becomes more complex [6–10]. In the inelastic region, a resonance is associated with a cluster of poles on different Riemann sheets. If one of these poles is located near the real axis and far enough from thresholds, it will be strongly dominant. We postpone the discussion on this until section II where a two-channel Breit-Wigner form of scattering amplitude will be used to give a pedagogical explanation.

Resonance parameters are extracted from partial wave amplitudes. The often used methods are based on the Breit-Wigner form[12], speed plot method of Hoehler[13, 14], and time delay method of Wigner[15, 16], which extract resonance parameters directly from partial wave amplitudes and need not a reaction model. Another method uses the dispersion relations, which was the basis of many analysis[17] of pion production data in the $\Delta$ region and is revived recently to also analyze $\eta$ production reactions[18]. For investigating the data at higher energy, where the production of two pions and other mesons could occur, the isobar model was developed to extract parameters of higher
mass nucleon resonances [19]. K-matrix method and isobar parameterization is used to perform amplitude analysis of the data and determine resonance parameters by SAID[20] and MAID[21]. Multi-channel K-matrix method[2, 4, 22] and unitary coupled-channel isobar model[3, 23] have been also developed.

From the resonance parameters listed by the Particle Data Group[24], it is clear that only the low-lying N* states are well established while there are large uncertainties in higher mass nucleon resonances. There are 13 “4-star” and 5 “3-star” N* and ∆ resonances below the mass of 2 GeV and another 6 “1- and 2-star” resonances at the same mass region. The Breit-Wigner parameters are most often quoted and are used in model-based studies of the baryons and associated reaction dynamics. The conventional parameters are the mass $m_R$, the width $\Gamma(E)$ at $E = m_R$, and the branching ratios. Following is one example of the problems with this conventional parametrization.

The Breit-Wigner mass, width and the pole position of $N^*(1440)P_{11}$, so-called Roper resonance, on Particle Listings by PDG[24] are extracted from several partial wave analyses of $\pi N$ scattering data. The pole position can be related to the mass and width of the resonance by

$$m_R = \text{Re} \, E_{\text{pole}}, \quad \Gamma = -2 \text{Im} \, E_{\text{pole}},$$

which is the origin of the denominator in a Breit-Wigner parametrization of a resonance.

By comparing the mass and width parameters to the position of the pole, one can see large discrepancies. The mass as extracted from the pole is estimated from 1350 to 1380 MeV, which lies typically about 80 MeV below $m_R$. Something similar can be seen by comparing the widths: here a ratio $-\Gamma / \text{Im} \, E_{\text{pole}} \sim 4$ is found instead of the expected value of 2. For an undistorted resonance, such as the $N^*(1520)D_{13}$, the mass and width from the Breit-Wigner parametrization and the pole position are essentially the same within a few MeV. This observation shows already that the Roper resonance is substantially influenced by strong meson-baryon non-resonant interactions and effects from nearby thresholds.

Höhler suggested the use of the pole position as source of information on the mass and width of a resonance, since the pole has a well-defined meaning in S-matrix theory[25]. Around 1440 MeV, the VPI group found two poles in the $P_{11}$ amplitude on different Riemann sheets[26]. Cutkosky et al. pointed out that the branch point for $\pi \Delta$ channel is located near the poles, so the poles belong to the same resonance[27]. Such meson-
baryon non-resonant interactions and effects from nearby threshold described above can be understood by a dynamical coupled channel model of meson production reactions that accounts for the off-shell scattering effects. It can therefore provide a much more direct way to interpret the resonance parameters.

The purpose of this work is to develop an analytic continuation method for meson production reactions and extract resonance parameters such as mass, width, electromagnetic transition form factors from the the $\pi N - \pi N$ and $\gamma^* N - \pi N$ amplitudes. We analyse $\pi N$ and $\gamma^* N$ reactions up to 2 GeV to study $N^*$ below 2 GeV. Above $\Delta(1232)P_{33}$ resonance, the dominant final states of those reactions are $\pi N$, $\eta N$ and $\pi\pi N$ states. The reaction model developed in Ref. [28–31] include $\pi N$ and $\eta N$ and also unstable particle channels $\sigma N$, $\rho N$ and $\pi \Delta$ to account for $\pi\pi N$. The model satisfies $\pi\pi N$ three body unitarity. To analytic continue to amplitude obtained form the above model, in addition to the stable particles channel such as $\pi N$ and $\eta N$ the unstable particle channels, $\sigma N$, $\rho N$ and $\pi \Delta$, which decay into $\pi\pi N$ channel. In the previous works on hyper nuclei[32] and $N - \Delta$ [33] system, unstable channels are treated as quasi two-body channel with complex mass and the decay of those states into three-body channel was only approximately included by introducing constant width. No analytic continuation method has been applied for extraction of $N^*$ mass and form factor from the dynamical model in the previous works. In this work we develop an method to analytic continuation of the amplitude including those unstable channel. We then apply the method for the scattering amplitude obtained from the analysis of the $\pi N$ of VPI and $\pi N$ cross section and $\gamma^* N$ cross sections obtained from JLab. We extract mass, width and the electromagnetic $N - N^*$ transition form factors.

In section II, we review the analytic structure of S-matrix and resonance phenomena which appears as the pole of S-matrix on unphysical energy sheet and develop an analytic continuation method by using some dynamical models. In section III, we present the method to extract resonance parameters as the residue of poles on amplitudes which are $N-N^*$ transition form factors. In section IV, we present the model Hamiltonian of our formulation. It is derived from a set of Lagrangians by applying the unitary transformation method[34, 35]. The coupled-channel equations are derived from the model Hamiltonian and we explain the procedures for performing numerical calculations.
within our formulation. Section V is devoted to showing the results from applying the developed analytic continuation method to extract the nucleon resonances in partial waves within our dynamical coupled channel model. Finally, a summary is given in section VI.

II. RESONANCE AND ANALYTIC STRUCTURE OF S-MATRIX

A. Scattering and resonance

Resonance phenomena are observed in scattering experiments of atomic, nuclear and particle physics. At first, we briefly review the pole structure of S-matrix within the framework of non-relativistic quantum dynamics. Let us consider the elastic scattering of a spinless particle by a target and assume that the interaction is represented by a potential \( V(r) \) which is spherically symmetric. Time-independent Schrödinger equation for S-wave scattering is written as

\[
\frac{-\nabla^2}{2m} + V(r) \psi(\vec{r}) = E \psi(\vec{r}),
\]

or

\[
-\frac{1}{2m} \frac{d^2}{dr^2} + V(r) \ u_k(r) = \frac{k^2}{2m} u_k(r),
\]

where the scattering wave function satisfies \( \psi(\vec{r}) = u_k(r)/r \) and a total energy is \( E = k^2/2m \). We assume that the potential \( V(r) \) vanishes identically at all distances larger than some finite distance \( R \),

\[ V(r) = 0 \quad \text{for} \quad r > R. \]

For \( r > R \), the solution of Eq. (3) is given by

\[ u_k(r) = A e^{ikr} + B e^{-ikr}, \]

which represents an outgoing and an incoming spherical wave. Here we define the S-matrix as

\[
\frac{d u_k}{dr} = N i k [S e^{ikr} + e^{-ikr}],
\]

\[
N | S e^{ikr} - e^{-ikr}|,
\]
where $N$ is a normalization factor. At $r = R$, it is clear that

\[
\frac{1}{ik} \frac{du_k(R)}{dr} + u_k(R) = 2NSe^{ikR},
\]

\[
\frac{1}{ik} \frac{du_k(R)}{dr} - u_k(R) = 2Ne^{-ikR},
\]

and we can easily obtain the expression of S-matrix,

\[
S = e^{-2ikR} \frac{du_k(R)}{dr} + ik u_k(R)
\]

\[\frac{du_k(R)}{dr} - ik u_k(R),\]

Assuming there is a bound state at $E = -B < 0$ and no incoming wave, Eq. (3) can be solved as

\[
u_B(r) = Ae^{ik_B r}
\]

\[
u_B(r) = Ae^{-\kappa_B r},
\]

with $k_B = i\kappa_B$ and $\kappa_B > 0$. Then the S-matrix for a bound state is given by

\[
S = e^{-2ikR - \kappa_B + ik} \frac{du_k(R)}{dr} - i k u_k(R)
\]

which has a pole at $k = -\kappa_B$ on the complex momentum plane. The pole that corresponds to a bound state exists on the imaginary axis of the complex momentum plane and the imaginary part of the pole position is positive.

Next, we assume some complex energy $E_n$ and corresponding complex momentum $k_n$, which satisfies $E_n = k_n^2/2m$ and Re $k_n > 0$. The above Schrödinger equation for $r > R$ can be solved as

\[
u_{k_n}(r) = Ae^{ik_n r} + Be^{-ik_n r},
\]

and

\[
\frac{du_{k_n}}{dr} = ik[Ae^{ik_n r} - Be^{-ik_n r}].
\]

It is easily to derive the boundary condition at $r = R$,

\[
u_{k_n}(R) - \frac{1}{ik_n} \frac{du_{k_n}(R)}{dr} = 2Be^{-ik_n R}.
\]

If we assume that there is no incoming wave, that is $B = 0$, the resulting boundary condition is

\[
u_{k_n}(R) - \frac{1}{ik_n} \frac{du_{k_n}(R)}{dr} = 0,
\]
which means the S-matrix represented by Eq. (10) diverges at the pole on complex momentum plane, \( k = k_n \). At this condition, the scattering wave function is

\[
u_k(r) = A e^{i k_R r - k_I r},
\]

where \( k = k_R + i k_I \).

As a function of energy \( E \), \( S \) is not single-valued, because it has different values for \( k \) and \(-k\), which belong to the same energy. We must therefore replace the complex \( E \) plane by a Riemann surface of two sheets, linked by a branch point at the origin. It is convenient to think of each sheet as covering the \( E \) plane once, with a cut along the positive real axis. Then the first sheet corresponds to the half plane in \( k \) above the real axis. This is usually called physical sheet, which contains no poles except those belonging to real bound states[36]. On the other hand, the second sheet corresponds to the half plane in \( k \) below the real axis, which is called unphysical sheet and can contain resonance poles.

**B. Analytic structure of S-matrix**

To examine analytic properties of S-matrix, we consider a commonly used two-channel Breit-Wigner (BW) amplitude [6, 8, 37, 38] which can be naturally derived from the coupled channel equation. To make the contact with what we will discuss in this thesis, we will indicate here how this amplitude can be derived from a Hamiltonian formulation of meson-baryon reactions, such as that developed in Ref.[28].

It is sufficient to consider the simplest two-channel case with a non-relativistic two-particle Hamiltonian defined by

\[
H = H_0 + V.
\]

In the center of mass frame \( H_0 \) can be written as

\[
H_0 = \sum_i |i\rangle [m_{i1} + m_{i2} + \frac{p^2}{2\mu_i}] \langle i|,
\]

where \( m_{ik} \) is the mass of \( k \)-th particle in channel \( i \), and \( \mu_i = m_{i1} m_{i2} / (m_{i1} + m_{i2}) \) is the reduced mass. In each partial-wave, the S-matrix is a \( 2 \times 2 \) matrix and can be written

\[
S = \frac{1 - i\pi\rho K}{1 + i\pi\rho K},
\]

where \( K \) is the momentum of the incoming particle.
where $\rho$ is the density of state, and the K-matrix, which is also a $2 \times 2$ matrix, is defined by the following Lippmann-Schwinger equation

$$K(E) = V + V \frac{P}{E - H_0} K(E). \quad (22)$$

Here $P$ means taking the principal-value of the integration over the propagator.

We now consider the on-shell matrix element of the S-matrix Eq. (21). If the on-shell momentum is denoted as $p_i$ for channel $i$, we then have

$$\langle i | 1 \pm i \pi \rho | j \rangle = \delta_{i,j} \pm i \pi \rho_i K_{i,j}, \quad (23)$$

where $\rho_i = p_i \mu_i$. The S-matrix element of the $1 \rightarrow 1$ elastic scattering is then of the following explicit form

$$S_{11} = \frac{(1 - i \pi \rho_1 K_{11})(1 + i \pi \rho_2 K_{22}) - \pi^2 \rho_1 \rho_2 K_{12} K_{21}}{(1 + i \pi \rho_1 K_{11})(1 + i \pi \rho_2 K_{22}) - \pi^2 \rho_1 \rho_2 K_{11} K_{22}}. \quad (24)$$

If we assume that at energies near the resonance energy the K-matrix can be approximated as

$$K_{ij} \approx g_i g_j \frac{E}{E - M}, \quad (25)$$

where $M$ is a mass parameter which is a real number, Eq. (24) can then be written as

$$S_{11} = \frac{E - M - i p_1 \gamma_1 + i p_2 \gamma_2}{E - M + i p_1 \gamma_1 + i p_2 \gamma_2}. \quad (26)$$

Here we have defined $\gamma_i = \pi g_i^2 \mu_i > 0$. If we further assume that $\gamma_i$ is independent of scattering energy, Eq. (26) is the commonly used two-channel Breit-Wigner formula[37, 38, 40]. Here, we will follow these earlier works and treat $\gamma_1$ and $\gamma_2$ as energy independent parameters of the model.

Since the scattering T-matrix is related to the S-matrix by

$$S_{11}(E) = 1 + 2i T_{11}(E), \quad (27)$$

Eq.(26) leads to

$$T(E) = \frac{-\gamma_1 p_1}{E - M + i \gamma_1 p_1 + i \gamma_2 p_2}. \quad (28)$$
From now we use the notation $T(E)$ for the $1 \rightarrow 1$ amplitude $T_{11}(E)$.

Within the two-channels Breit-Wigner model specified above, we will examine the analytic properties of the S-matrix on the complex energy $E$-plane. This will also allow us to explain clearly some terminologies which are commonly seen but often not explicitly explained in the literatures on resonance extractions.

The on-shell momenta $p_i$ for channel $i$ is defined by

$$E_i = \frac{p_i^2}{2\mu_i}, \quad (29)$$

where

$$E_i = E - (m_{i1} + m_{i2}). \quad (30)$$

We can define the threshold variable $\Delta$ between two channels by

$$E_1 = \frac{p_2^2}{2\mu_2} + \frac{\Delta^2}{2\mu_1}, \quad (31)$$

where

$$\frac{\Delta^2}{2\mu_1} = m_{21} + m_{22} - m_{11} - m_{12} \quad (32)$$

is the threshold energy of the second channel.

The momenta at poles of the S-matrix Eq. (26) can be determined by solving

$$E - M + ip_1\gamma_1 + ip_2\gamma_2 = 0. \quad (33)$$

By using Eqs. (29)-(32), the above equation can be written as

$$p_1^4 + ap_1^3 + bp_1^2 + cp_1 + d = 0, \quad (34)$$

where

$$a = i4\mu_1\gamma_1, \quad (35)$$

$$b = 4\mu_1(\mu_2\gamma_2^2 - M - \mu_1\gamma_1^2), \quad (36)$$

$$c = -8i\mu_1^2M\gamma_1, \quad (37)$$

$$d = 4(\mu_1^2M^2 - \mu_1\mu_2\gamma_2^2\Delta^2). \quad (38)$$

Eq. (34) means that the Breit-Wigner amplitude Eq. (26) has four poles. Each pole is specified by two on-shell momenta $P_\alpha = (p_{1\alpha}, p_{2\alpha})$ with $\alpha = 1, 2, 3, 4$. The analytic
properties of the S-matrix Eq. (26) depends on how these poles are located on the complex energy $E$-plane. The energy plane for each channel has two Riemann sheets because of the quadratic relation Eq. (29) between the momentum $p_i$ and energy $E_i$; namely $p_i = \sqrt{2\mu_i |E_i|} e^{i\phi_i}/2$ for $i = 1, 2$. For each channel, the physical ($p$) sheet is defined by specifying the range of phase $0 \leq \phi_i \leq 2\pi$, and the un-physical ($u$) sheet by $2\pi \leq \phi_i \leq 4\pi$. The correspondence between the momentum $p_i$-plane and the energy $E_i$-plane is similar to that illustrated in Fig. 1. For the considered two-channel case, we thus have four energy sheets specified by the signs of $\text{Im} p_1$ and $\text{Im} p_2$: $pp$, $up$, $uu$, and $pu$, as shown in Fig. 2. Thus each of four poles $P_\alpha = (p_{1\alpha}, p_{2\alpha})$ can be on one of these $E$-sheets.

To be more specific, we now consider the case which is most relevant to our study of nucleon resonances. That is the $\text{Re} E_1 > 0$ and $\text{Re} E_2 > 0$ case that the poles are all above the thresholds of both channels. From Eq. (33), we immediately notice that if $(p_{1a}, p_{2a})$ with $E = E_a$ is one of the solutions, $(-p_{1a}^*, -p_{2a}^*)$ with $E = E_a^*$ is also a solution. Therefore the four poles determined by Eq. (34) can be grouped into two pairs. In the following discussions, they are denoted as $(E_a, E_a^*)$ and $(E_b, E_b^*)$. Without losing generality, one can assume that one of the poles is in the range of $(\text{Re} p_1 > 0, \text{Re} p_2 > 0)$ and the other in the range of $(\text{Re} p_1 < 0, \text{Re} p_2 < 0)$. If the first pole $(p_{1a}, p_{2a})$ is in the region where $(\text{Re} p_{1a} > 0, \text{Re} p_{2a} > 0)$ and $(\text{Im} p_{1a} < 0, \text{Im} p_{2a} < 0)$, it is a pole, denoted as $E_R$, on the $uu$-sheet of Fig. 2. This pole is usually called the resonance pole and is closer than other poles on $up$ or $pu$-sheets to the physical $pp$-sheet, as will be explained later. In the Hamiltonian formulation considered in this work and the well developed collision theory, a resonance pole can be mathematically derived[11] from the mechanism that an unstable system is formed and decay subsequently during the collision. The resonance pole $E_R$ has an accompanied pole $E^*_R$ at $(-p_{1a}^*, -p_{2a}^*)$ which is also on the $uu$-sheet as shown in Fig. 2. $E^*_R$ is called the ’conjugate pole’ of $E_R$.

The second pole at $(p_{1b}, p_{2b})$ with $\text{Im} p_{1b} < 0$ and $\text{Im} p_{2b} > 0$ ( $\text{Im} p_{1b} > 0$ and $\text{Im} p_{2b} < 0$) may be on the $up$-sheet ($pu$-sheet), depending on the parameters $\gamma_1$ and $\gamma_2$. This pole is called the shadow pole[39]. A shadow pole on $up$-sheet and its conjugate pole are $E_S$ and $E^*_S$ in Fig. 2.

We now note that in this simple BW model, the zeros of the S-matrix Eq. (26), where
\( S_{11}(E) = 0 \), is defined by its numerator

\[
E - M - ip_1 \gamma_1 + ip_2 \gamma_2 = 0.
\]  
(39)

The above equation can be cast into the form of Eq. (33) by simply replacing \( p_1 \) by \(-p_1\). Thus solutions of Eq. (39), called the zeros of S-matrix, can be readily obtained from the solutions \((p_{1a}, p_{2a})\) and \((p_{1b}, p_{2b})\) of Eq. (33). They are \((-p_{1\alpha}, p_{2\alpha})\) with \( E_\alpha \) and \((p_{1\alpha}^*, -p_{2\alpha}^*)\) with \( E_\alpha^* \) for \( \alpha = a, b \). The zero at \((-p_{1b}, p_{2b})\) is on the pp-sheet, denoted as \( E_{ZS} \) and \( E_{ZS}^* \) in Fig. 2. Similarly, the zero at \((-p_{1a}, p_{2a})\) is on the pu-sheet, shown as \( E_{ZR} \) together with its conjugate \( E_{ZR}^* \) in Fig. 2. Note that Fig. 2 is for the case that the parameters \( \gamma_1 \) and \( \gamma_2 \) are chosen such that the shadow poles \( E_S \) and its conjugate \( E_S^* \) are on the up-sheet. For other possible \( \gamma_1 \) and \( \gamma_2 \), the pole positions could be different from what are shown in Fig. 2, but their close relations, as discussed above, are the same.

From the above analysis, it is clear that the poles and zeros of the S-matrix are closely related. Their locations on the 4 Riemann sheets can be conveniently displayed on one complex plane by introducing a variable \( t \)[36]

\[
p_1 = \Delta \frac{1 + t^2}{1 - t^2},
\]  
(40)

\[
p_2 = 2\Delta \sqrt{\frac{\mu_2}{\mu_1}} \frac{t}{1 - t^2}.
\]  
(41)

Hence each point in the \( t \)-plane corresponds to a set of \((p_1, p_2)\). In Fig. 3, the resonance position \( E_R \) and shadow \( E_S \) poles and their conjugate poles and zeros of S-matrix \( E_{ZS}, E_{ZR}, E_{ZS}^*, E_{ZR}^* \) are shown on t-plane. The physical S-matrix at real energies, which determine the observables, are on the bold lines. The zero energy and the threshold of the second channel correspond to \( t = i \) and \( t = 0 \), respectively. One can see that the resonance pole \( E_R \) is closer than the shadow pole \( E_S \) to the bold lines (S-matrix) and hence can have the largest effect on the observables. Consequently, most of the rapid energy dependence of observables are attributed to the resonance poles, not the shadow poles or the other poles shown in Fig.3. On the other hand, the zero \( E_{ZS}^* \) of the S-matrix is also close to the bold lines. As seen in the derivations given above, this zero \( E_{ZS}^* \) is closely related to shadow pole \( E_S \). Thus the shadow poles can also be related to the observables. Of course, which pole is most important in determining the rapid energy dependence of observables also depends on the residues of the T-matrix at the pole positions.
Next, we will use a further simplified BW form to explain more clearly the close relations between the poles and zeros of the S-matrix. In particular we will see explicitly that the shadow pole $E_S$ in Fig. 2, which is not on the same Riemann sheet as $E_R$, can be located by the zeros of the S-matrix.

For simplicity, we assume that the threshold energies of the two channels are the same and hence $\mu \equiv \mu_1 = \mu_2$ and $\Delta = 0$. Therefore we have simple relations between energy and momenta: $E = p_1^2/2\mu = p_2^2/2\mu$ and $p \equiv p_1 = \pm p_2$. The four Riemann sheets are classified by the sign of the imaginary part of the momentum; namely, physical (unphysical) sheet is assigned by $\text{Im} p > 0$ ($\text{Im} p < 0$). With the simplification $p \equiv p_1 = \pm p_2$, we obviously have $p_1 = p_2 = p$ on the $pp$ and $uu$-sheets, and $p_1 = -p_2 = p$ on $up$ and $pu$-sheets.
Let us start with the case of $p_1 = p_2 = p$ for the $pp$-sheet or $uu$-sheet. The S-matrix element Eq. (26) of the first channel can be written as

$$S_{11}(E) = \frac{E - M - i(\gamma_1 - \gamma_2)p}{E - M + i(\gamma_1 + \gamma_2)p}. \quad (42)$$

It can be cast into the following more transparent form

$$S_{11}(E) = \frac{(p + p_S)(p - p_S^*)}{(p - p_R)(p + p_R^*)}, \quad (43)$$

with

$$p_R = \sqrt{2\mu M - (\mu \gamma_+)^2 - i\mu \gamma_+}, \quad (44)$$

$$p_S = \sqrt{2\mu M - (\mu \gamma_-)^2 - i\mu \gamma_-}. \quad (45)$$
where
\[ \gamma_\pm = \gamma_1 \pm \gamma_2. \] (46)

Remembering that we consider \( \gamma_1 > 0 \) and \( \gamma_2 > 0 \). To make use of Fig.2 in the following discussion, we consider the case that \( \gamma_1 > \gamma_2 \) and hence \( \gamma_\pm > 0 \) and both \( p_R \) and \( p_S \) defined in Eqs. (44)-(45) are associated with the unphysical \( u \)-sheet. For the case of \( \gamma_\gamma < 0 \), \( p_S \) is associated with the physical \( p \)-sheet and the following presentation can be easily modified to account for this case.

Clearly, Eq. (43) means that the S-matrix has a pole at \( p_1 = p_2 = p = p_R \) on the \( uu \)-sheet with a resonance energy
\[ E_R = \frac{p_R^2}{2\mu} = M - \mu \gamma_+^2 - i\gamma_+ \sqrt{\mu(2M - \mu \gamma_+^2)}. \] (47)

Its conjugate pole \( E_R^* \) is at \( p_1 = p_2 = p = -p_R^* \). The positions of \( E_R \) and \( E_R^* \) are shown in the upper right side of Fig.2. Eq. (43) also indicates that the zero of S-matrix is at \( p_1 = p_2 = -p_S \) which is on the \( pp \)-sheet because of \( \text{Im}(-p_S) > 0 \). The energy of this zero of S-matrix is
\[ E_{ZS} = \frac{p_S^2}{2\mu} = M - \mu \gamma_-^2 - i\gamma_- \sqrt{\mu(2M - \mu \gamma_-^2)}. \] (48)

Its conjugate \( E_{ZS}^* \) is at \( p_1 = p_2 = p_S^* \). The positions of \( E_{ZS} \) and \( E_{ZS}^* \) are on the \( pp \)-sheet, as shown in the upper left side of Fig.2.

We next consider the \( p_1 = -p_2 = p \) case that the poles and zeros of the S-matrix are on the \( up \) or \( pu \)-sheets. The S-matrix Eq. (26) for this case then takes the following form
\[ S_{11}(E) = \frac{E - M - i(\gamma_1 + \gamma_2)p}{E - M + i(\gamma_1 - \gamma_2)p}. \] (49)

By comparing Eq. (42) and Eq. (49) and using the variables \( p_R \) and \( p_S \) defined by Eqs. (44) and (45), Eq. (49) can be written as
\[ S_{11}(E) = \frac{(p + p_R)(p - p_R^*)}{(p - p_S)(p + p_S^*)}. \] (50)

The above equation indicates that for the considered \( \gamma_- > 0 \), the S-matrix has a shadow pole at \( p_1 = -p_2 = p = p_S \) on the \( up \)-sheet. Thus its position \( E_S = p_S^2/(2\mu) \) is identical to \( E_{ZS} \) of the zero of the S-matrix on the \( pp \)-sheet; namely
\[ E_S = E_{ZS} = \frac{p_S^2}{2\mu} = M - \mu \gamma_-^2 - i\gamma_- \sqrt{\mu(2M - \mu \gamma_-^2)}. \] (51)
This means that the shadow pole $E_S$ on the up-sheet can be found from searching for the zero $E_{ZS}$ of S-matrix on the pp-sheet.

Eq. (50) also gives a zero of S-matrix at $p_1 = -p_2 = p = -p_R$ on $pu$-plane because $\text{Im}(-p_R) > 0$. Its energy $E_{ZR}$ is also identical to $E_R$ defined above

$$E_{ZR} = E_R = \frac{p_R^2}{2\mu} = M - \mu \gamma_+^2 - i\gamma_+\sqrt{\mu(2M - \mu \gamma_+^2)}.$$ 

The positions of $E_S$ and $E_{ZR}$ and their conjugates $E^{*}_S$ and $E^{*}_{ZR}$ are also in the lower parts of Fig.2.

From the above analysis for the $\gamma_- > 0$ case, we see that the energies of the resonance poles may be obtained by studying the poles of the S-matrix on the uu-sheet and those of the shadow poles may be obtained from the zeros of the S-matrix on the pp-sheet. The analysis for the $\gamma_- < 0$ case is similar. Here we only mention that when $\gamma_- > 0$ is changed to $\gamma_- < 0$, the shadow poles $E_S$ and $E^*_S$ on the up-sheet move to the pu-sheet and zeros $E_{ZS}$ and $E^*_{ZS}$ will be on the uu-sheet.

C. Analytic continuation method for dynamical models

With the analysis presented in the previous subsection, it is clear that the empirical partial-wave amplitudes determined from experimental data can not be blindly used to extract resonance parameters. To make progress, one needs to construct a reaction model to fit the data and then extract the resonance parameters by analytic continuation within the model. Our task in this subsection is to develop numerical methods for finding the resonance poles from dynamical coupled-channel models which do not have analytical forms of their solutions. We will first consider the simplest single-channel case, then two-channel coupled case and finally unstable channels coupled case.

1. Single-channel

To be specific, we consider the two-particle reactions defined by the following well known isobar Hamiltonian in the center of mass frame

$$H = H_0 + H',$$ 

(53)
C Analytic continuation method for dynamical models

with

\[ H_0 = [E_1(p) + E_2(-p)] + |N_0\rangle M_0 \langle N_0|, \quad (54) \]

\[ H' = |g\rangle \langle g|, \quad (55) \]

where \( M_0 \) is the mass parameter of a bare particle \( N_0 \) which can decay into two particle states through the vertex interaction \( g \) in \( H' \), and \( E_i(p) = [m_i^2 + p^2]^{1/2} \) is the energy of the \( i \)-th particle. The scattering operator is defined by

\[ t(E) = H' + H' \frac{1}{E - H_0 - H' H'}, \quad (56) \]

which leads to the following Lippmann-Schwinger equation for the scattering amplitudes in each partial-wave

\[ t(p', p; E) = v(p', p; E) + \int_{C_0} dq \frac{v(p', q; E)t(q, p; E)}{E - E_1(q) - E_2(q)}, \quad (57) \]

where the integration path \( C_0 \) will be specified later. The interaction in Eq. (57) is

\[ v(p', p; E) = \frac{g(p')g(p)}{E - M_0}. \quad (58) \]

Eqs. (57)-(58) leads to the following well known solution

\[ t(p', p; E) = \frac{g(p')g(p)}{E - M_0 - \Sigma(E)}, \quad (59) \]

with

\[ \Sigma(E) = \int_{C_0} dp \frac{p^2 g^2(p)}{E - E_1(p) - E_2(p)}. \quad (60) \]

The resonance poles can be found from \( t(E) = t(p_0, p_0; E) \) on the unphysical Riemann sheet defined by \( \text{Im} \, p_0 < 0 \) with \( p_0 \) denoting the on-shell momentum

\[ E = \sqrt{m_1^2 + p_0^2} + \sqrt{m_2^2 + p_0^2}. \quad (61) \]

Obviously \( p_0 \) is also the pole position of the propagator in Eq. (57) or Eq. (60).

The physical scattering amplitude at a positive energy \( E \) can be obtained from Eq. (57) or Eq. (59) by setting \( E \rightarrow E + i\epsilon \) with a positive \( \epsilon \rightarrow 0 \) and choosing the integration contour \( C_0 \) to be along the real-axis of \( p \) with \( 0 \leq p \leq \infty \). From Eq. (57) it is clear that \( t(E) \) has a discontinuity on the positive real \( E \)

\[ \text{Dis}(t(E)) = t(E + i\epsilon) - t(E - i\epsilon) \]

\[ = 2\pi i\rho(p_0)v(p_0, p_0)t(E), \quad (62) \]
where $\rho(p_0) = p_0 E_1(p_0) E_2(p_0)/E$. Thus the t-matrix has a cut running along the real positive $E$. To find resonance poles, we need to find the solution of Eq. (57) on the unphysical sheet with $\text{Im } p \leq 0$ on which the pole $p_0$ of the propagator moves into the lower $p$-plane, as shown in (a) of Fig. 4. From Eq. (62), it is clear that the solution of Eq. (57), with the contour $C_0$ chosen to be on the real-axis $0 \leq p \leq \infty$, will encounter the discontinuity and is not the solution on the unphysical sheet where we want to search for the resonance poles. It is well-known\cite{40–43} that this difficulty can be overcame by deforming the integration path to the contour $C_1'$ shown in (a) of Fig. 4. By this the pole will not cross the cut and the integral is analytically continued from real positive $E$ to the lower half of the unphysical $E$-sheet with $\text{Im } p_0 \leq 0$. Obviously, the same solution can be obtained by choosing any contour which is below the pole position $p_0$, such as the contour $C_1$ of (b) of Fig. 4.

With the solution of the form of Eq. (59), the numerical procedure of finding resonance poles is to solve

$$E - M_0 - \Sigma(E) = 0.$$  \hfill (63)
with

\[ \Sigma(E) = \int_{C_1} dp \frac{g^2(p)}{E - E_1(p) - E_2(p)} \]

(64)

and

\[ \Sigma(E) = \int_{C_1} dp \frac{g^2(p)}{E - E_1(p) - E_2(p)}, \]

(65)

for \( E \) on the unphysical Riemann sheet defined by \( \text{Im} \, p_0 \leq 0 \). To test this numerical procedure, let us consider the case that \( \Sigma(E) \) defined by Eq. (60) can be calculated analytically. Such an analytic form can be obtained by taking the non-relativistic kinematics \( E_1(p) + E_2(p) = m_1 + m_2 + p^2/(2\mu) \) with \( \mu = m_1 m_2/(m_1 + m_2) \) and a monopole form for the vertex function

\[ g(p) = \frac{\lambda}{1 + p^2/\beta^2}, \]

(66)

where \( \beta \) is a cut-off parameter. The integration in \( \Sigma(E) \) of Eq. (60) can then be done exactly to give the following simple form

\[ \Sigma(E) = \frac{\pi \mu \beta^3 \lambda^2}{2(p_0 + i\beta)^2}, \]

(67)

where \( p_0 \) is defined by \( E = m_1 + m_2 + p_0^2/(2\mu) \). If the imaginary part of \( p_0 \) is positive (negative), it means that we choose the poles on physical (unphysical) sheet. Only the pole with \( \text{Im} \, p_0 \leq 0 \) on the unphysical sheet is called resonance.

2. Two-channel coupled system

The formula for two-channels, one-resonance case can be easily obtained by extending the equations in the case of one-channel. We introduce channel label \( i = 1, 2 \) and thus have

\[ t_{ij}(p', p; E) = v_{ij}(p', p; E) + \sum_k \int dq \frac{v_{ik}(p', q) t_{kj}(q, p; E)}{E - E_{k1}(q) - E_{k2}(q)}, \]

(68)

where \( E_{kn}(p) = [m_{kn}^2 + p^2]^{1/2} \) with \( m_{kn} \) denoting the mass of \( n \)-th particle in channel \( k \), and

\[ v_{ij}(p', p; E) = g_i(p') \frac{1}{E - M_0} g_j(p). \]

(69)

Eqs. (68)-(69) leads to

\[ t_{ij}(p', p; E) = \frac{g_i(p') g_j(p)}{E - M_0 - \Sigma_1(E) - \Sigma_2(E)}, \]

(70)
II. RESONANCE AND ANALYTIC STRUCTURE OF S-MATRIX

with

\[ \Sigma_k(E) = \int_{c_0} dp \frac{g_k^2(p)}{E - E_{k1}(p) - E_{k2}(p)}. \]  

(71)

For the physical scattering amplitude at a positive energy \( E \), Eq. (68) is solved by setting \( E \to E + i\epsilon \) with a positive \( \epsilon \to 0 \) and choosing \( C_0 \) along the real axis \( 0 \leq p \leq \infty \).

With Eq. (70), the poles of the scattering amplitudes are defined by

\[ E - M_0 - \Sigma_1(E) - \Sigma_2(E) = 0. \]  

(72)

The poles from solving the above equation can be on one of the four Riemann sheets, \( pp, up, uu, \) and \( pu \). The numerical procedure for finding the resonance poles on \( uu \)-sheet is to solve Eq. (72) for \( E = E_{i1}(p_{01}) + E_{i2}(p_{02}) = E_{21}(p_{02}) + E_{22}(p_{02}) \) with \( \text{Im} \, p_{01} \leq 0 \) and \( \text{Im} \, p_{02} \leq 0 \). The integration path \( C_0 \) is changed to \( C_1 \) shown in (b) of Fig.4 to calculate both self-energies \( \Sigma_1(E) \) and \( \Sigma_2(E) \) of Eq. (71). Of course the contour \( C_1 \) for the integration over the momentum for \( i \)-th channel must be below the pole \( p_{0i} \) defined by \( E - E_{i1}(p_{0i}) - E_{i2}(p_{0i}) = 0 \). Here we note that for finding the poles on \( pu \)-sheet (\( up \)-sheet), the contour \( C_0 \) is replaced by \( C_1 \) only for \( \Sigma_2(E) \) (\( \Sigma_1(E) \)).

To test the pole trajectory, let us consider again the non-relativistic kinematics \( E_{i1}(p) + E_{i2}(p) = m_{i1} + m_{i2} + p^2/(2\mu_i) \) with \( \mu_i = m_{i1}m_{i2}/(m_{i1} + m_{i2}) \). This will allow us to find the exact solutions by choosing the monopole form factor

\[ g_i(p) = \frac{\lambda_i}{1 + p^2/\beta_i^2}. \]  

(73)

We then have

\[ \Sigma_i(E) = \frac{\pi \mu_i/\beta_i^2 \lambda_i^2}{2(p_i + i\beta_i)^2}. \]  

(74)

With Eq. (74), the poles defined by Eq. (72) can be found by solving algebraic equations.

For numerical calculations, we consider a case similar to \( \pi N \) scattering in \( S_{11} \) partial wave: (1)channel-1 is \( \pi N \) with \( m_{11} = m_\pi = 139.6 \) MeV , \( m_{12} = m_N = 938.5 \) MeV, and \( \beta_1 = 800 \) MeV, (2)channel-2 is \( \eta N \) with \( m_{21} = m_\eta = 547.45 \) MeV , \( m_{22} = m_N = 938.5 \) MeV, and \( \beta_2 = 800 \) MeV, (3) bare mass \( M_0 = m_\pi + m_N + 600 \) MeV. The results are shown in Fig.5. The dash-dotted (solid) curves are the calculated poles on \( uu \)-sheet (\( up \)-sheet) with the coupling constants \( \lambda_1 = 0.02 \) for \( N_0 \to \pi N \) and a range of \( \lambda_2 = 0 - 0.02 \).
for $N_0 \to \eta N$. We see that when $\lambda_2$ is 0, which is the single-channel case, the $uu$-pole and the $up$-pole are on the same position. They then split as $\lambda_2$ increases.

We next evaluate Eq. (71) for $E$ on the $uu$-sheet, $up$-sheet or $pu$-sheet by appropriately choosing the path $C_0$, as described above. The poles are found when the calculated $\Sigma_1(E)$ and $\Sigma_2(E)$ satisfy Eq. (72). We find that the poles obtained by this numerical procedure reproduce accurately the dash-dotted($uu$-sheet), solid($up$-sheet) and dashed($pu$-sheet) curve in Fig.5 and hence are omitted there. Thus this analytic continuation method can be used in practice to find the resonance poles.

In Fig.5, the poles on the $uu$-sheet are represented by dash-dotted curve. The poles on the $up$-sheet and $pu$-sheet are represented by the solid curve and the dashed curve respectively. One can show[11] that the poles on $uu$-sheet are due to the process that an unstable system is created and then decays during the collision and are called the resonance poles. The physical interpretations of the poles on $pu$ and $up$-sheets remain to be developed.

It is interesting to point out here that the two-channel Breit-Wigner form analyzed...
II RESONANCE AND ANALYTIC STRUCTURE OF S-MATRIX

In detail in the previous subsection can be derived from the two-channels, one-resonance model if the non-relativistic kinematics is used. To see this, we first write the non-relativistic relation between the S-matrix and the T-matrix

\[ S_{ij}(E) = \delta_{ij} + 2i T_{ij}(E), \]  
\[ T_{ij}(E) = -\pi \sqrt{\mu_i \mu_j} \eta_{ij}(p_i, p_j; E), \]  

where \( p_i \) is the on-shell momentum in channel \( i \)

\[ p_i = \sqrt{2\mu_i(E - m_{i1} - m_{i2})}. \]

With the above and the analytic form Eq. (74) for \( \Sigma_i(E) \), we can write the \( 1 \to 1 \) elastic scattering amplitude of Eq. (76) as

\[ T_{11}(p_1, p_2, E) = \frac{-p_1 \gamma_1(p_1)}{E - M(E) + ip_1 \gamma_1(p_1) + ip_2 \gamma_2(p_2)}, \]  

where \( \gamma_i(p_i) = \pi \mu_i g_i^2(p_i) > 0 \) and

\[ M(E) = M^0 + \sum_k P \int p^2 dp \frac{g_k^2(p)}{E - m_{k1} - m_{k2} - \frac{p^2}{2\mu_k}} \]

where \( P \) means taking the principal-value integration. By using Eq. (75), we then have the \( 1 \to 1 \) elastic part of the S-matrix

\[ S_{11} = \frac{E - M(E) - ip_1 \gamma_1(p_1) + ip_2 \gamma_2(p_2)}{E - M(E) + ip_1 \gamma_1(p_1) + ip_2 \gamma_2(p_2)}. \]

If the E-dependence of \( M(E) \) and \( \gamma_i(p_i) \) are further neglected, Eqs. (78) and (80) are identical to what are usually called the two-channel Breit-Wigner resonant amplitude discussed in the previous subsection.

3. Dynamical model with unstable particle channels

For meson-baryon reactions, the nucleon resonances can decay into some unstable particle channels such as the \( \pi \Delta, \rho N, \sigma N \) considered in the model of Ref.[28]. Here we discuss the analytic continuation method to find resonance poles within such a reaction model.

It is sufficient to consider the one-channel and one resonance case. The scattering formula is then identical to that presented above. The only difference is that one of the
particles in the open channel can further decay into a two particle state. To be specific, let us consider the $\pi\Delta$ channel. Within the same Hamiltonian formulation[28], the scattering amplitude can then be written as

$$t(p', p, E) = \frac{g_{N^*\pi\Delta}(p')g_{N^*\pi\Delta}(p)}{E - M_0 - \Sigma_{\pi\Delta}(E)}$$

with

$$\Sigma_{\pi\Delta}(E) = \int_{C_2} p^2 dp \frac{g_{N^*\pi\Delta}(p)^2}{E - E_\pi(p) - E_\Delta(p) - \Sigma_{\Delta}(p, E)}$$

where

$$\Sigma_{\Delta}(p, E) = \int_{C_3} q^2 dq \frac{g_{\Delta\pi N}(q)^2}{E - E_\pi(p) - [(E_\pi(q) + E_N(q))^2 + q^2]^{1/2}}.$$  

To obtain the $\pi\Delta$ self energy for complex $E$, the analytic structure of the integrand of Eq. (82) should be examined first. The discontinuity of the $\pi\Delta$ propagator in the integrand of Eq. (82) is the $\pi\pi N$ cut along the real axis between $\pm p_0$ ($-p_0 \leq p \leq p_0$) which is obtained by solving

$$E = E_\pi(p_0) + [(m_\pi + m_N)^2 + p_0^2]^{1/2}. \quad (84)$$

For finding the resonance poles on $uu$-sheet with $\text{Im} p_0 \leq 0$, the integration contour $C_2$ of Eq. (82) must be chosen below this cut which is the dashed line in Fig.6. There is also a singularity in the integrand of Eq. (82) at momentum $p = p_x$, which satisfies

$$E - E_\pi(p_x) - E_\Delta(p_x) - \Sigma_{\Delta}(p_x, E) = 0. \quad (85)$$

Physically, this singularity corresponds to the $\pi\Delta$ two-body scattering state. For $E$ with large imaginary part, $p_x$ can be below the $\pi\pi N$ cut as also indicated in Fig.6. Therefore the integration contour of momentum $p$ must be chosen to be below the $\pi\pi N$ cut (dashed line) and the singularity $p_x$, such as the contour $C_2$ shown in Fig.6.

The singularity position $q_0$ of the propagator in Eq. (83) depends on spectator momentum $p$

$$E - E_\pi(p) = [(E_\pi(q_0) + E_N(q_0))^2 + q^2]^{1/2}. \quad (86)$$

Therefore the singularity $q_0$ moves along the dashed curve in Fig.7 when the momentum $p$ varies along the path $C_2$ of Fig.6. To analytically continue $\Sigma_{\Delta}(p, E)$ from positive energy
FIG. 6: Contour $C_2$ for calculating the $\pi\Delta$ self energy on unphysical sheet. See the text for the explanations of the dashed line and the singularity $p_x$.

FIG. 7: Contour $C_3$ for calculating the $\pi N$ self energy on the unphysical sheet. Dashed curve is the singularity $q_0$ of the propagator in Eq. (83), which depends on the spectator momentum $p$ on the contour $C_2$ of Fig. 6.

$E$ to the un-physical plane with Im $p \leq 0$, we need to choose the contour $C_3$ of Eq. (83) which must be below $q_0$. A possible contour $C_3$ is the solid curve in Fig. 7.

To verify the numerical procedures described above, we again consider non-relativistic
kinematics and monopole form factor. With the similar analytic form Eq. (67), we have
\[
\Sigma_{\Delta}(p, E) = \frac{\pi \mu_{\pi N} g_{\Delta, \pi N}^2 \beta_{\Delta, \pi N}^3}{2(k + i\beta_{\Delta, \pi N})^2}
\] (87)
where
\[
k = \left[2\mu_{\pi N} \left(E - 2m_\pi - m_N - \frac{p^2}{2\mu_{\pi N}} - \frac{\pi \mu_{\pi N} g_{\Delta, \pi N}^2 \beta_{\Delta, \pi N}^3}{2(k + i\beta_{\Delta, \pi N})^2}\right)\right]^{1/2},
\] (88)
with \(\mu_{\pi N} = m_\pi(m_\pi + m_N)/(2m_\pi + m_N)\). With Eq. (87), we can solve Eq. (85) and verify its relation with \(\pi \pi N\) cut as discussed above and illustrated in Fig.6. Eq. (87) and the chosen monopole form factor also allow us to get
\[
\Sigma_{\pi \Delta} = \int_{c_2} p^2 dp \frac{g_{N^*, \pi \Delta}^2}{(1 + p^2/\beta_{N^*, \pi \Delta}^2)^2} \frac{1}{D_{\pi \Delta}(p, E)}
\] (89)
with
\[
D_{\pi \Delta}(p, E) = E - m_{\pi} - m_{\Delta} - \frac{p^2}{2\mu_{\pi \Delta}} - \frac{\pi \mu_{\pi N} g_{\Delta, \pi N}^2 \beta_{\Delta, \pi N}^3}{2(k + i\beta_{\Delta, \pi N})^2}.
\] (90)
Unfortunately, Eq. (89) can not be integrated out analytically for directly checking our numerical procedure for searching resonance poles.

We test our analytic continuation method by the following procedure. We calculate Eq. (89) numerically to find the pole position \(E_R\) by solving \(E_R - M_0 - \Sigma_{\pi \Delta}(E_R) = 0\) of the denominator of Eq. (81). With the parameters:
\[
\beta_{N^*, \pi \Delta} = 800\,\text{MeV}, \quad g_{N^*, \pi \Delta} = 0.02\,\text{MeV}^{-1/2}, \quad g_{\Delta, \pi N} = 0.05\,\text{MeV}^{-1/2},
\]
\[
M_0 = 650\,\text{MeV} + m_{\pi} + m_N,
\]
we find \(E_R = (1679.1, -33.6i)\) MeV. The pole position is obtained numerically by Newton’s method in Appendix A. We then construct an approximate propagator
\[
G_{N^*}^{\text{approx}}(E) = \frac{1}{E - E_R}.
\] (91)
For the positive E, we find that \(G_{N^*}^{\text{approx}}(E)\) is in good agreement with the direct calculation of \(G_{N^*}(E) = 1/(E - M_0 - \Sigma_{\pi \Delta}(E))\) by using Eq. (89). The results are shown in Fig.8. It is clear that the resonance pole found by our analytic continuation method can reproduce what is expected for a resonance propagator for real positive E. In this way our numerical procedure is justified and can be applied to solve Eqs. (81) - (83).
III. EXTRACTION OF RESONANCE PARAMETERS

The complex resonance energy is the position of the pole of the scattering amplitude which is on the Riemann sheet nearest to the physical sheet. In this section, we explain how the residues of resonance poles are extracted from a dynamical model and how the transition form factor of the resonance are defined by the residue.

A. Pole expansion of scattering amplitudes

We assume that scattering amplitude $T$ is written as the sum of meson-exchange non-resonant amplitude $t^{\text{non-res}}$ and resonant amplitude, which is expressed by $N^*$ propagator $1/D(E)$ and the vertex between $N^*$ and a final meson-baryon state $\bar{\Gamma}_f$ or an initial meson-baryon state $\bar{\Gamma}_i$,

$$ T = t^{\text{non-res}} + \bar{\Gamma}_f \bar{\Gamma}_i D(E), \quad (92) $$

$$ D(E) = E - M_0 - \Sigma(E), \quad (93) $$

where $M_0$ is the mass of the bare resonance which is not coupled with meson-baryon continuum state and $\Sigma(E)$ is the selfenergy of $N^*$. The resonance energy $M$ is given as
the pole position of the propagator on complex energy plane,

\[ D(M) = 0. \]  \hspace{1cm} (94)

We can write the amplitude near resonance pole by Laurent expansion as

\[ T(E) = \frac{R}{E - M} + C_0 + C_1(E - M) + \cdots, \]  \hspace{1cm} (95)

where

\[ R = \frac{\bar{\Gamma}_f(M)\bar{\Gamma}_i(M)}{D'(M)}, \]  \hspace{1cm} (96)

\[ C_0 = t_{\text{non-res}}(M) + \frac{\bar{\Gamma}_f(M)\bar{\Gamma}_i(M) + \Gamma_f(M)\Gamma_i(M)}{D'(M)} - \frac{D''(M)}{2(D'(M))^2}\bar{\Gamma}_f(M)\bar{\Gamma}_i(M). \]  \hspace{1cm} (97)

Then the resonance form factor which describes the transition into channel \( c \) can be written as

\[ F_c(W) = \frac{\Gamma_c(M)}{\sqrt{D'(M)}}. \]  \hspace{1cm} (98)

The above expressions are valid in the case of the meson-baryon system coupled with one \( N^* \). Expressions for two \( N^* \)'s are given in Appendix B.

\[ B \quad \text{N-N* transition form factor} \]

The residue of the \( \pi N \) elastic scattering amplitude characterizes the strength of the coupling of the resonance with \( \pi N \) channel and the transition form factor of \( N^* \) can be obtained in terms of the residue of the pole on complex energy plane. We apply the procedure of the pole expansion to a dynamical coupled channel model which describes \( MB \) or \( \gamma N \rightarrow \pi N \) reactions. The details of our dynamical model will be given in Section IV, so here we present essential points of the model for extracting resonance parameters.

In our dynamical model the scattering amplitude of meson-baryon states from \( MB \) to \( M'B' \) is written as the sum of a non-resonant and a resonant amplitude,

\[ T_{M'B',MB}(p',p,E) = t_{\text{non-res}}^{M'B',MB}(p',p,E) + t_{\text{res}}^{M'B',MB}(p',p,E). \]  \hspace{1cm} (99)

The resonant amplitude is given as

\[ t_{\text{res}}^{M'B',MB}(p',p,E) = \sum_{i,j} \hat{\Gamma}_{M'B',i} |D(E)|_{i,j} \hat{\Gamma}_{MB,j} \]  \hspace{1cm} (100)
where we sum bare nucleon resonance states \( i, j \). The propagator of the resonant state \( N^* \) is

\[
[D(E)^{-1}]_{ij}(E) = (E - M_{N^*}^0)\delta_{ij} - \Sigma_{ij}(E),
\]

where \( M_{N^*}^0 \) is the bare mass of \( N^* \) and \( \Sigma_{ij}(E) \) is the selfenergy. So far we found resonance from the resonant amplitude and the resonance energy \( M \) is determined from

\[
\det[D(M)^{-1}] = 0.
\]

The scattering amplitude \( \pi N \) and \( \gamma N \rightarrow \pi N \) amplitudes can be written near the resonance energy \( M \) by using the Laurent expansion as

\[
T_{M'B'MB}(p_{M'B'}^0, p_{MB}^0, M) = C^{-1}_{M'B'MN} \frac{E}{E - M} + C^0_{M'B'MB} + C^1_{M'B'MB}(E - M) + \cdots,
\]

where \( p^0 \) is the on-shell momentum for the total energy \( E \).

The first term in Eq. (103) represents the resonance pole and the next order correction term is the constant \( C^0 \). The above expression will be useful in the \( E \) region where we have no other singularity of \( T(E) \). For example, the applicability of the above formula can be limited by the opening of a new channel. \( C^{-1} \) is the residue of the amplitude and given as

\[
C^{-1}_{M'B'MB} = \Gamma^{R}_{M'B'MB},
\]

where \( \chi_i \) is the eigenfunction of the inverse of \( N^* \) propagator and satisfies

\[
\sum_j (M_{N^*}^0 \delta_{ij} + \Sigma_{ij}(M))\chi_j = M\chi_i.
\]

We can approximate the propagator of \( N^* \) around the pole with this \( \chi_i \) as

\[
[D(E)]_{ij} \sim \frac{\chi_i \chi_j}{E - M}.
\]

If there is only one bare \( N^* \) state, it is easy to see that

\[
\chi = \frac{1}{\sqrt{1 - \Sigma'(M)}},
\]
where $\Sigma'(M) = [d\Sigma/dE]_{E=M}$. The constant term $C^0$ in Eq. (103) has contributions from non-resonant and resonant amplitudes, that is

$$C_0 = t^{\text{non-res}}(p_{MB}^0, M) + \frac{\partial}{\partial W} \left[ \sum_{i,j} \Gamma_{M'B',i}(p_{M'B'}^0, W)G_{N,i}^j(W)\bar{\Gamma}_{MB,i}(p_{MB}^0, W)(W - M) \right] \bigg|_{W=M}.$$  

The relation between $\pi N$ elastic scattering amplitude $F_{\pi N,\pi N}$ with on-shell momentum and S-matrix is given by

$$F_{\pi N,\pi N}(E) = -\pi \frac{p^0 E_N(p^0)E_\pi(p^0)}{E} T_{\pi N,\pi N}(p^0, p^0, E)$$

and

$$F_{\pi N,\pi N}(E) = \frac{S_{\pi N,\pi N}(E) - 1}{2i}.$$  

The residue of the resonance pole on scattering amplitude satisfies

$$\lim_{E \to M} F_{\pi N,\pi N}(E) \simeq \frac{Re^{i\phi}}{M - E},$$  

and

$$Re^{i\phi} = \frac{\pi p^0 E_N(p^0)E_\pi(p^0)}{M} \bar{\Gamma}_R\bar{\Gamma}_R \bar{\pi}_N \bar{\pi}_N.$$  

Thus we can obtain the residue $Re^{i\phi}$ of the resonance pole on complex energy plane. The relation between the residue and the transition form factor $\bar{\Gamma}_R \bar{\Gamma}_R \bar{\pi}_N$ is also given.

### IV. DYNAMICAL MODEL OF MESON PRODUCTION REACTIONS

#### A. Model Hamiltonian

In this subsection we present a model Hamiltonian for constructing a coupled-channel reaction model with $\gamma N$, $\pi N$, $\eta N$ and $\pi\pi N$ channels. Since significant parts of the $\pi\pi N$ production are known experimentally to be through the unstable states $\pi \Delta$, $\rho N$ and $\sigma N$, we will also include bare $\Delta$, $\rho$ and $\sigma$ degrees of freedom in our formulation. Furthermore, we introduce bare $N^*$ states to represent the quark-core components of the nucleon resonances. The model is expected to be valid up to $E = 2 \text{ GeV}$ below which $\pi\pi N$ production is dominant and we neglect $KY$, $\omega N$ and three pion production processes.
Similar to the model of Refs. [34, 45] (commonly called the SL model), our starting point is a set of Lagrangians describing the interactions between mesons ($M = \gamma, \pi, \eta, \rho, \sigma$) and baryons ($B = N, \Delta, N^* \cdots$). These Lagrangian are constrained by various well-established symmetry properties, such as the invariance under isospin, parity, and gauge transformation. The chiral symmetry is also implemented as much as we can. The considered Lagrangians are given in Appendix C. By applying the standard canonical quantization, we obtain a Hamiltonian of the following form

$$H = \int h(\vec{x}, t = 0) d\vec{x}$$

$$= H_0 + H_I,$$

(115)

where $h(\vec{x}, t)$ is the Hamiltonian density constructed from the starting Lagrangians and the conjugate momentum field operators. In Eq.(115), $H_0$ is the free Hamiltonian and

$$H_I = \sum_{M,B,B'} \Gamma_{MB \rightarrow B'} + \sum_{M,M',M''} h_{M',M'' \rightarrow M},$$

(116)

where $\Gamma_{MB \rightarrow B'}$ describes the absorption and emission of a meson($M$) by a baryon($B$) such as $\pi N \leftrightarrow N$ and $\pi N \leftrightarrow \Delta$, and $h_{M',M'' \rightarrow M}$ describes the vertex interactions between mesons such as $\pi\pi \leftrightarrow \rho$ and $\gamma\pi \leftrightarrow \pi$. Clearly, it is a non-trivial many body problem to calculate meson-baryon scattering and meson production reaction amplitudes from the Hamiltonian defined by Eqs.(115)-(116). To obtain a manageable reaction model, we apply a unitary transformation method[34, 35] to derive an effective Hamiltonian from Eqs.(115)-(116). The essential idea of the employed unitary transformation method is to eliminate the unphysical vertex interactions $MB \rightarrow B'$ with masses $m_M + m_B < m_{B'}$ from the Hamiltonian and absorb their effects into $MB \rightarrow M'B'$ two-body interactions. The resulting effective Hamiltonian is energy independent and hence is easy to be used in developing reaction models and performing many-particle calculations. The details of this method is explained in the Appendix of Ref.[34].

Our main step is to derive from Eqs.(115)-(116) an effective Hamiltonian which contains interactions involving $\pi\pi N$ three-particle states. This is accomplished by applying the unitary transformation method up to the third order in interaction $H_I$ of Eq.(116). The resulting effective Hamiltonian is of the following form

$$H_{eff} = H_0 + V,$$

(117)
A Model Hamiltonian

with

\[ H_0 = \sum_{\alpha} K_{\alpha}, \]  

(118)

where \( K_{\alpha} = \sqrt{m_{\alpha}^2 + p_{\alpha}^2} \) is the free energy operator of particle \( \alpha \) with a mass \( m_{\alpha} \), and

the interaction Hamiltonian is

\[ V = \Gamma_V + v_{22} + v', \]  

(119)

where

\[ \Gamma_V = \left\{ \sum_{N^* \to MB} \left( \Gamma_{N^* \to MB} + \Gamma_{N^* \to \pi\pi N} \right) + \sum_{M^*} h_{M^* \to \pi\pi} \right\} + \{ \text{c.c.} \}, \]  

(120)

\[ v_{22} = \sum_{MB,M'B'} v_{MB,M'B'} + v_{\pi\pi}. \]  

(121)

Here \( \text{c.c.} \) denotes the complex conjugate of the terms on its left-hand-side. In the above equations, \( MB = \gamma N, \pi N, \eta N, \pi\Delta, \rho N, \sigma N \) represent the considered meson-baryon states. The resonance associated with the bare baryon state \( N^* \) is induced by the vertex interactions \( \Gamma_{N^* \to MB} \) and \( \Gamma_{N^* \to \pi\pi N} \). Similarly, the bare meson states \( M^* = \rho, \sigma \) can develop into resonances through the vertex interaction \( h_{M^* \to \pi\pi} \). These vertex interactions are illustrated in Fig.9(a). Note that the masses \( M^0_{N^*} \) and \( m^0_{M^*} \) of the bare states \( N^* \) and \( M^* \) are the parameters of the model which will be determined by fitting the \( \pi N \) and \( \pi\pi \) scattering data. They differ from the empirically determined resonance positions by mass shifts which are due to the coupling of the bare states with the meson-baryon scattering states. It is thus reasonable to speculate that these bare masses can be identified with the mass spectrum predicted by the hadron structure calculations which do not account for the meson-baryon continuum scattering states, such as the calculations based on the constituent quark models which do not have meson-exchange quark-quark interactions.

In Eq. (121), \( v_{MB,M'B'} \) is the non-resonant meson-baryon interaction and \( v_{\pi\pi} \) is the non-resonant \( \pi\pi \) interaction. They are illustrated in Fig. 9(b). The third term in Eq. (119) describes the non-resonant interactions involving \( \pi\pi N \) states

\[ v' = v_{23} + v_{33} \]  

(122)

with

\[ v_{23} = \sum_{MB} \left[ \left( v_{MB,\pi\pi N} \right) + \{ \text{c.c.} \} \right] \]

\[ v_{33} = v_{\pi\pi N,\pi\pi N}. \]
FIG. 9: Basic mechanisms of the Model Hamiltonian defined in Eqs. (120)-(122).

FIG. 10: Mechanisms for $v_{MB,M'B'}$ of Eq. (121): (a) direct s-channel, (b) crossed u-channel, (c) one-particle-exchange t-channel, (d) contact interactions.

They are illustrated in Fig. 9(c). All of these interactions are defined by the tree-diagrams generated from the considered Lagrangians. They are illustrated in Fig. 10 for two-body interactions $v_{MB,M'B'}$ and in Fig. 11 for $v_{MB,\pi\piN}$. Some leading mechanisms of $v_{\pi\pi}$ and $v_{\pi\piN,\pi\piN}$ are illustrated in Fig. 12. The matrix elements of these interactions are calculated from the usual Feynman amplitudes with their time components in the propagators of intermediate states defined by the three momenta of the initial and final states, as specified by the unitary transformation methods. Thus they are independent of the collision energy $E$.

B. Two body $MB \rightarrow MB$ amplitude

With the Hamiltonian defined by Eqs. (117)-(122), we follow the formulation of Ref. [11] to define the scattering S-matrix as

$$S_{ab}(E) = \delta_{ab} - (2\pi)iT_{ab}(E),$$

(123)
FIG. 11: Examples of non-resonant mechanisms of $v_{MN,\pi\pi N}$ with $M = \pi$ or $\gamma$ (denoted by long-dashed lines). $M_I$ denotes the intermediate mesons ($\pi, \rho, \omega$).

\[
v_{\pi\pi} = \ldots \rho, \sigma \ldots
\]

\[
v_{\pi\pi N,\pi\pi N} = \ldots + \ldots + \ldots + \ldots
\]

FIG. 12: Examples of non-resonant mechanisms of $v_{\pi\pi}$ and $v_{\pi\pi N,\pi\pi N}$

where the scattering T-matrix is defined by

\[
T_{ab}(E) = <a|T(E)|b>
\]

with

\[
T(E) = V + V \frac{1}{E - H_0 + i\epsilon} T(E).
\]

(124)

Since the interaction $V$, defined by Eqs. (119)-(122), is energy independent, it is rather straightforward to follow the formal scattering theory given in Ref. [11] to show that
Eq. (124) leads to the following unitarity condition

\[
(T(E) - T^\dagger(E))_{ab} = -2\pi i \sum_c T^\dagger_{ac}(E)\delta(E_c - E)T_{cb}(E),
\]

where \(a, b, c\) are the reaction channels in the considered energy region.

Our task is to derive from Eq. (124) a set of dynamical coupled-channel equations for practical calculations within the model space \(N^* \oplus MB \oplus \pi\pi N\). In the derivations, the unitarity condition Eq. (125) must be maintained exactly. We achieve this rather complex task by applying the standard projection operator techniques[12], similar to that employed in a study[46] of \(\pi NN\) scattering. The details of our derivations are given in Appendix B of Ref. [28]. To explain the coupled-channel equations, it is sufficient to present the formula obtained from setting \(\Gamma_{MB \rightarrow \pi\pi N} = 0\) in the derivations. The resulting model is defined by Eqs. (B74)-(B96) in Appendix B of Ref. [28]. Here we explain these equations and discuss their dynamical content.

The resulting \(MB \rightarrow M' B'\) amplitude \(T_{MB \rightarrow M' B'}\) in each partial wave is illustrated in Fig. 13. It can be written as

\[
T_{MB, M' B'}(E) = t_{MB, M' B'}(E) + t^R_{MB, M' B'}(E),
\]

(126)

The second term in the right-hand-side of Eq.(126) is the resonant term defined by

\[
t^R_{MB, M' B'}(E) = \sum_{N^*_i, N^*_j} \bar{\Gamma}_{MB \rightarrow N^*_i}(E)[D(E)]_{i,j} \bar{\Gamma}_{N^*_j \rightarrow M' B'}(E),
\]

(127)

with

\[
[D(E)^{-1}]_{i,j}(E) = (E - M^0_{N^*_j})\delta_{i,j} - \bar{\Sigma}_{i,j}(E),
\]

(128)

where \(M^0_{N^*_j}\) is the bare mass of the resonant state \(N^*_j\), and the self-energies are

\[
\bar{\Sigma}_{i,j}(E) = \sum_{MB} \Gamma_{N^*_j \rightarrow MB} G_{MB}(E) \bar{\Gamma}_{MB \rightarrow N^*_i}(E).
\]

(129)

The dressed vertex interactions in Eq.(127) and Eq.(129) are (defining \(\Gamma_{MB \rightarrow N^*_j} = \Gamma^\dagger_{N^*_j \rightarrow MB}\))

\[
\bar{\Gamma}_{MB \rightarrow N^*_j}(E) = \Gamma_{MB \rightarrow N^*_j} + \sum_{M' B'} t_{MB, M' B'}(E) G_{M' B'}(E) \Gamma_{M' B' \rightarrow N^*_j},
\]

(130)

\[
\bar{\Gamma}_{N^*_j \rightarrow MB}(E) = \Gamma_{N^*_j \rightarrow MB} + \sum_{M' B'} \Gamma_{N^*_j \rightarrow M' B'} G_{M' B'}(E) t_{M' B', MB}(E).
\]

(131)
The meson-baryon propagator $G_{MB}$ in the above equations takes the following form

$$G_{MB}(E) = \frac{1}{E - K_B - K_M - \Sigma_{MB}(E) + i\epsilon},$$

where the mass shift $\Sigma_{MB}(E)$ depends on the considered $MB$ channel. It is $\Sigma_{MB}(E) = 0$ for the stable particle channels $MB = \pi N, \eta N$. For channels containing an unstable particle, such as $MB = \pi \Delta, \rho N, \sigma N$, we have

$$\Sigma_{MB}(E) = [\langle MB|g_V \frac{P_{\pi \pi N}}{E - K_\pi - K_\pi - K_N + i\epsilon} g_V^\dagger|MB \rangle]_{\text{un-connected}}$$

with

$$g_V = \Gamma_{\Delta \to \pi N} + h_{\rho \to \pi \pi} + h_{\sigma \to \pi \pi}.$$

In Eq. (133) "un-connected" means that the stable particle, $\pi$ or $N$, of the $MB$ state is a spectator in the $\pi \pi N$ propagation. Thus $\Sigma_{MB}(E)$ is just the mass renormalization of the unstable particle in the $MB$ state.

It is important to note that the resonant amplitude $t_{MB',MB}^R(E)$ is influenced by the non-resonant amplitude $t_{MB',MB}(E)$, as seen in Eqs. (127)-(131). In particular,
Eqs. (130)-(131) describe the meson cloud effects on $N^*$ decays, as illustrated in Fig. 14 for the $\Delta \rightarrow \gamma N$ decay interpreted in Refs. [34, 45]. This feature of our formulation is essential in interpreting the extracted resonance parameters.

The non-resonant amplitudes $t_{MB,M'B'}$ in Eq. (126) and Eqs. (130)-(131) are defined by the following coupled-channel equations

$$t_{MB,M'B'}(E) = V_{MB,M'B'}(E) + \sum_{M''B''} V_{MB,M''B''}(E)G_{M''B''}(E)t_{M''B'',M'B'}(E) \quad (135)$$

with

$$V_{MB,M'B'}(E) = v_{MB,M'B'} + Z_{MB,M'B'}(E). \quad (136)$$

Here $Z_{MB,M'B'}(E)$ contains the effects due to the coupling with $\pi\pi N$ states. It has the following form

$$Z_{MB,M'B'}(E) = < MB | \frac{P_{\pi\pi N}}{E - H_0 - \bar{v}_{\pi\pi N} + i\epsilon} F^\dagger | M'B'>$$

$$- [\delta_{MB,M'B'}\Sigma_{MB}(E)] \quad (137)$$
Two body MB $\rightarrow$ MB amplitude

with

$$\hat{v}_{\pi\pi N} = v_{\pi N,\pi N} + v_{\pi\pi \pi \pi N,\pi N} ,$$  \hspace{1cm} (138)

$$F = g_V + v_{MB,\pi\pi N} ,$$  \hspace{1cm} (139)

where $g_V$ has been defined in Eq. (134). Note that the second term in Eq. (137) is the effect which is already included in the mass shifts $\Sigma_{MB}$ of the propagator Eq. (132) and must be removed to avoid double counting.

The appearance of the projection operator $P_{\pi\pi N}$ in Eqs. (133) and (137) is the consequence of the unitarity condition Eq. (125). To isolate the effects entirely due to the vertex interaction $g_V = \Gamma_{\Delta N} + h_{\rho N} + h_{\sigma N}$, we use the operator relation Eq. (B33) of Appendix B in Ref. [28] to decompose the $\pi\pi N$ propagator of Eq. (137) to write

$$Z_{MB,M'B'}(E) = Z^{(E)}_{MB,M'B'}(E) + Z^{(I)}_{MB,M'B'}(E) .$$  \hspace{1cm} (140)

The first term is

$$Z^{(E)}_{MB,M'B'}(E) = <MB | g_V \frac{P_{\pi\pi N}}{E - H_0 + i\epsilon} g_V^\dagger | M'B'> - [\delta_{MB,M'B'} \Sigma_{MB}(E)] .$$  \hspace{1cm} (141)

Obviously, $Z^{(E)}_{MB,M'B'}(E)$ is the one-particle-exchange interaction between unstable particle channels $\pi\Delta$, $\rho N$, and $\sigma N$, as illustrated in Fig. 15. The second term of Eq. (140) is

$$Z^{(I)}_{MB,M'B'}(E) = <MB | F \frac{P_{\pi\pi N}}{E - H_0 + i\epsilon} t_{\pi\pi N,\pi N}(E) \frac{P_{\pi\pi N}}{E - H_0 + i\epsilon} F^\dagger | M'B'>$$

$$+ <MB | g_V \frac{P_{\pi\pi N}}{E - H_0 + i\epsilon} v_{MB,\pi\pi N}^\dagger | B'M'>$$

$$+ <MB | v_{MB,\pi\pi N} \frac{P_{\pi\pi N}}{E - H_0 + i\epsilon} g_V^\dagger | M'B'>$$

$$+ <MB | v_{MB,\pi\pi N} \frac{P_{\pi\pi N}}{E - H_0 + i\epsilon} v_{MB,\pi\pi N}^\dagger | M'B'> .$$  \hspace{1cm} (142)

Some of the leading terms of $Z^{(I)}_{MB,M'B'}(E)$ are illustrated in Fig. 16. Here $t_{\pi\pi N,\pi N}(E)$ is a three-body scattering amplitude defined by

$$t_{\pi\pi N,\pi N}(E) = \hat{v}_{\pi\pi N} + \hat{v}_{\pi\pi N} \frac{1}{E - K_\pi - K_\pi - K_N - \hat{v}_{\pi\pi N} + i\epsilon} \hat{v}_{\pi\pi N}$$  \hspace{1cm} (143)

where $\hat{v}_{\pi\pi N}$ has been defined in Eq. (138). Few leading terms of Eq. (143) due to the direct s-channel interaction $v^s$ of $v_{\pi N,\pi N}$ are shown in Fig. 17. These terms involve the
IV DYNAMICAL MODEL OF MESON PRODUCTION REACTIONS

\[ Z_{MB,M'B'}^{(E)} = \Delta + \rho, \sigma \]

FIG. 15: One-particle-exchange interactions \( Z_{\pi \Delta}^{(E)}(E) \), \( Z_{\rho N, \pi \Delta}^{(E)} \) and \( Z_{\rho N, \pi \Delta}^{(E)} \) of Eq. (141).

\[ Z_{MB,M'B'}^{(I)} = \]

FIG. 16: Examples of mechanisms included in \( Z_{MB,M'B'}^{(I)}(E) \) of Eq. (142).

\( \pi \pi N \) propagator \( 1/(E - K_{\pi} - K_{\pi} - K_{N} + i\epsilon) \) and obviously can generate \( \pi \pi N \) cut effects which are due to the \( \pi \pi N \) vertex. This observation indicates that the \( \pi N \) scattering equation of Aaron, Amado and Young\(^{47}\) can be related to our formulation if the interactions which are only determined by the \( \pi \pi N \) vertex are kept in the equations presented above.

C. MB \( \rightarrow \pi \pi N \) amplitudes

The amplitudes \( T_{MB,M'B'} = t_{MB,M'B'} + t_{MB,M'B'}^{R} \) defined by Eq. (126) can be used directly to calculate the cross sections of \( \pi N \rightarrow \pi N, \eta N \) and \( \gamma N \rightarrow \pi N, \eta N \) reactions. They are also the input to the calculations of the two-pion production amplitudes. The
two-pion production amplitudes resulted from our derivations given in Appendix B of Ref. [28] are illustrated in Fig. 18. They can be cast exactly into the following form

\[
T_{\pi\pi N,MB}(E) = T^{\text{dir}}_{\pi\pi N,MB}(E) + T^{\Delta}_{\pi\pi N,MB}(E) + T^{\rho N}_{\pi\pi N,MB}(E) + T^{\sigma N}_{\pi\pi N,MB}(E) \quad (144)
\]

with

\[
T^{\text{dir}}_{\pi\pi N,MB}(E) = \langle \psi^{(-)}_{\pi\pi N}(E) | \sum_{M'B'} v_{\pi\pi N,M'B'}[\delta_{M'B',MB} \\
+ G_{M'B'}(E)(t_{M'B',MB}(E) + t_{R_{M'B',MB}}(E))] | MB \rangle , \quad (145)
\]

\[
T^{\Delta}_{\pi\pi N,MB}(E) = \langle \psi^{(-)}_{\pi\pi N}(E) | \Gamma^{\Delta}_{\Delta\pi\pi N} G_{\pi\pi}(E)[t_{\pi\Delta,MB}(E) + t_{R_{\pi\Delta,MB}}(E)] | MB \rangle , \quad (146)
\]

\[
T^{\rho N}_{\pi\pi N,MB}(E) = \langle \psi^{(-)}_{\pi\pi N}(E) | h^{\dagger}_{\rho \pi\pi N} G_{\rho N}(E)[t_{\rho N,MB}(E) + t_{R_{\rho N,MB}}(E)] | MB \rangle , \quad (147)
\]

\[
T^{\sigma N}_{\pi\pi N,MB}(E) = \langle \psi^{(-)}_{\pi\pi N}(E) | h^{\dagger}_{\sigma \pi\pi N} G_{\sigma N}(E)[t_{\sigma N,MB}(E) + t_{R_{\sigma N,MB}}(E)] | MB \rangle . \quad (148)
\]

In the above equations, the \( \pi\pi N \) scattering wave function is defined by

\[
< \psi^{(-)}_{\pi\pi N}(E) | = \langle \pi\pi N | \Omega^{(-)}_{\pi\pi N}(E) , \quad (149)
\]
where the scattering operator is defined by

\[ \Omega_{\pi\pi N}^{(-)}(E) = \langle \pi\pi N | [1 + t_{\pi\pi N,\pi\pi N}(E)\frac{1}{E - K_\pi - K_\pi - K_N + i\epsilon}] \rangle. \quad (150) \]

Here the three-body scattering amplitude \( t_{\pi\pi N,\pi\pi N}(E) \) is determined by the non-resonant interactions \( v_{\pi\pi}, v_{\pi N,\pi N} \) and \( v_{\pi N,\pi N}, v_{\pi N,\pi N} \), as defined by Eq. (143).

We note here that the direct production amplitude \( T_{\pi\pi N,MB}^{dir}(E) \) of Eq. (145) is due to \( v_{\pi N,MB} \) interaction illustrated in Fig. 11, while the other three terms are through the unstable \( \pi\Delta, \rho N, \) and \( \sigma N \) states. Each term has the contributions from the non-resonant amplitude \( t_{MB',MB}(E) \) and resonant term \( t_{MB',MB}^R(E) \). As seen in Eq. (127)-(131), the resonant amplitude \( t_{MB',MB}^R(E) \) is influenced by the non-resonant amplitude \( t_{MB',MB}(E) \). This an important consequence of unitarity condition Eq. (125).

D. Partial wave expansion of \( MB \rightarrow MB \) amplitudes

We solve Eq. (135) in the partial-wave representation. To proceed, we follow the convention of Goldberger and Watson[11] to normalize the plane-wave state \( |\vec{k}\rangle \) by
Clearly, Eqs. (155)-(156) lead to \[ \frac{d\sigma}{d\Omega} = \frac{(4\pi)^2}{k^2} \rho_{M'B'}(k') \rho_{MB}(k) \frac{1}{(2j_M + 1)(2j_B + 1)} \sum_{m_{j_M},m_{j_B};m'_{j_M},m'_{j_B}} \left| < M'B'|T(E)|MB > \right|^2 \]

(151)

with

\[ < M'B'|T(E)|MB > = < j'M'M'_J'; i'M'i'_J; j'_Bm'_j; \tau'_Bm'_\tau > T_{M'B',MB}(k', \bar{k}, E)|j_Mm_{j_M}; i_Mi_{i_M}; j_Bm_{j_B}; \tau_Bm_{\tau_B} > , \]

(152)

where \([(j_M, m_{j_M}), (i_M, i_{i_M})]\) and \([(j_Bm_{j_B}), (\tau_Bm_{\tau_B})]\) are the spin-isospin quantum numbers of mesons and baryons, respectively. The incoming and outgoing momenta \(k\) and \(k'\) are defined by the collision energy \(E\)

\[ E = E_M(k) + E_B(k) = E_M(k') + E_B(k') , \]

(153)

and the phase-space factor is

\[ \rho_{MB}(k) = \frac{\pi kE_M(k)E_B(k)}{E} . \]

(154)

The partial-wave expansion of the scattering amplitude is defined as

\[ T_{M'B',MB}(k', \bar{k}, E) = \sum_{j_M,T_M,T_S} \sum_{L_M,L'B'} \sum_{L_M,S_M} |Y^{J_M,T_M}_{L_M,J_M,J_B}(k')|T^{JT}_{L'S'M'B',LSMB}(k', k, E) < Y^{J_M,T_M}_{L_M,J_M,J_B}(\bar{k})| \]

(155)

where the total angular vector in the spin-isospin space is defined by

\[ |Y^{J_M,T_M}_{L_M,J_M,J_B}(\bar{k})| = \sum_{all \, m} |j_Mm_{j_M}, i_Mi_{i_M}; j_Bm_{j_B}, \tau_Bm_{\tau_B} > < T_M|i_M\tau_Bm_{i_M}m_{\tau_B} > \]

\[ \times < JM|LSm_{L}m_{S} > < Sm_{S}|j_Mj_Bm_{j_B}m_{j_B} > Y_{LM_L}(\bar{k}) . \]

(156)

Clearly, Eqs. (155)-(156) lead to

\[ T^{JT}_{L'S'M'B',LSMB}(k', k, E) = \int dk' \int d\bar{k} < Y^{J_M,T_M}_{L'M_J,J_B'}(k')|T_{M'B',MB}(k', \bar{k}, E)|Y^{J_M,T_M}_{L'M_J,J_B'}(\bar{k})| > . \]

(157)
By also expanding the driving term $V_{MB,M'B'}(\vec{k},\vec{k'},E)$ of Eq. (135) into the partial-wave form similar to Eq.(155), we then obtain a set of coupled one-dimensional integral equations

$$t_{LS'M'B',LSMB}'(k',k,E) = V_{LS'M'B',LSMB}'(k',k,E)$$

$$+ \sum_{M'B'} \sum_{L'S'} \int k'' dE' V_{LS'M'B',L'S'M'B'}(k',k'',E)$$

$$\times G_{M'B'}(k'',E) t_{L'S'M'B',LSMB}'(k'',k,E),$$

(158)

where the driving term is

$$V_{LS'M'B',LSMB}'(k',k) = v_{LS'M'B',LSMB}'(k',k) + Z^{(E)}_{LS'M'B',LSMB}'(k',k,E).$$

(159)

The above partial-wave matrix elements of the non-resonant interaction $v_{M'B',MB}$ and one-particle-exchange interaction $Z^{(E)}_{M'B',MB}(E)$ are given in Appendices C and E of Ref. [28], respectively. There the numerical methods for evaluating them are also discussed in some details; in particular on the use of the transformation from the helicity representation to the partial-wave representation.

The propagators in Eq.(158) are given by taking the matrix elements in Appendix B of Ref. [28] we have

$$G_{MB}(k,E) = \frac{1}{E - E_M(k) - E_B(k) + i\epsilon}$$

(160)

for stable particle channels $MB = \pi N, \eta N$, and

$$G_{MB}(k,E) = \frac{1}{E - E_M(k) - E_B(k) - \Sigma_{MB}(k,E)}$$

(161)

for unstable particle channels $MB = \pi \Delta, \rho N, \sigma N$ with

$$\Sigma_{\pi\Delta}(k,E) = \frac{m_\Delta}{E_{\pi\Delta}(k)} \int q^2 dq \frac{M_{\pi N}(q)}{[M^2_{\pi N}(q) + k^2]^{1/2} E - E_{\pi}(k) - [(E_N(q) + E_{\pi}(q))^2 + k^2]^{1/2} + i\epsilon},$$

(162)

$$\Sigma_{\rho N}(k,E) = \frac{m_{\rho}}{E_{\rho}(k)} \int q^2 dq \frac{M_{\pi}(q)}{[M^2_{\pi}(q) + k^2]^{1/2} E - E_N(k) - [(2E_{\pi}(q))^2 + k^2]^{1/2} + i\epsilon},$$

(163)

$$\Sigma_{\sigma N}(k,E) = \frac{m_{\sigma}}{E_{\sigma}(k)} \int q^2 dq \frac{M_{\pi}(q)}{[M^2_{\pi}(q) + k^2]^{1/2} E - E_N(k) - [(2E_{\pi}(q))^2 + k^2]^{1/2} + i\epsilon},$$

(164)

where the vertex function $f_{\Delta,\pi N}(q)$ is from Ref.[34], $f_{\rho,\pi N}(q)$ and $f_{\sigma,\pi N}(q)$ are from the isobar fits[48] to the $\pi\pi$ phase shifts. They are given in Appendix D of Ref. [28].
The solutions of Eq. (158) are then used to calculate the non-resonant photo-production amplitudes. Here we use the helicity-LSJ mixed-representation that the initial \( \gamma N \) state is specified by their helicities, \( \lambda_\gamma, \lambda_N \), but the final \( MB \) is defined by the \(( LS)J \) angular momentum variables

\[
v_{MB,\gamma N}(k, q) = \sum_{J M, T M} \sum_{\lambda, \lambda_N} \left| Y^{J M, T M}_{L (JM, JB)}(k) \right|^2 v^{JT}_{LSMB, \lambda, \lambda_N m_{m\gamma}}(k, q, E) \times \sqrt{\frac{2J + 1}{4\pi}} D^J_{M, (\lambda_\gamma - \lambda_N)}(\phi_q, \theta_q, -\phi_q) < \lambda_\gamma, \lambda_N m_{m\gamma} |,
\]

where \( D^J_{m, m'}(\phi, \theta, -\phi) = e^{i(m + m')\phi} d^j_{m, m'}(\theta) \) with \( d^j_{m, m'}(\theta) \) being the Wigner rotation function. Eq. (135) then leads to

\[
t^{JT}_{LSMB, \lambda, \lambda_N m_{m\gamma}}(k, q, E) = v^{JT}_{LSMB, \lambda, \lambda_N m_{m\gamma}}(k, q, E) + \sum_{MB'} \sum_{L' S'} \int_{US'} k'^2 dk' t^{JT}_{LSMB', L'S'M'B'}(k', k, E) \times G_{MB'}(k', E) v^{JT}_{L'S'M'B', \lambda, \lambda_N m_{m\gamma}}(k', q, E).
\]

The matrix elements \( v^{JT}_{LSMB, \lambda, \lambda_N m_{m\gamma}}(k, q, E) \) considered in our calculations are given in Appendix F of Ref. [28]. This unconventional representation, which is convenient for calculations, can be related to the usual multipole expansion, as also given in appendix G of Ref. [28].

E. JLMS model of \( \pi N \) scattering

The parameters of the hadronic interactions of the dynamical model described in the above subsections are given in Ref. [29]. The parameters are first determined by fitting the empirical \( \pi N \) elastic scattering amplitudes of SAID up to 2 GeV. Then the resulting parameters are refined by directly comparing the predicted differential cross section and target polarization asymmetry with the original data of the elastic \( \pi^+ p \rightarrow \pi^+ p \) and charge-exchange \( \pi^- p \rightarrow \pi^0 n \) processes.

We solve the coupled-channel equations defined in the previous section in the partial-wave representation. The input of these equations are the partial-wave matrix elements of \( \Gamma_{N^*-MB} \) and \( v_{MB, M'B'} \) of Eqs. (120)-(121), with \( MB, M'B' = \pi N, \eta N, \pi \Delta, \rho N, \sigma N \), and \( Z^{(E)}_{MB, M'B'} \) of Eq. (136) with \( MB, M'B' = \pi \Delta, \rho N, \sigma N \). The calculations of these
IV DYNAMICAL MODEL OF MESON PRODUCTION REACTIONS

The matrix elements have been given explicitly in the appendices of Ref. [28]. Here we only mention a few points which are needed for later discussions.

In deriving the non-resonant interactions $v_{MB,M'B'}$ of Eq. (136) we consider the tree-diagrams (Fig. 10) generated from a set of Lagrangians with $\pi$, $\eta$, $\sigma$, $\rho$, $\omega$, and $N$, and $\Delta$ fields. The higher mass mesons, such as $a_0$, $a_1$ included in other meson-exchange $\pi N$ models, such as the Jülich model [52], are not considered. The employed Lagrangians are given in Appendix C.

To solve the coupled-channel equations, Eq. (135), we need to regularize the matrix elements of $v_{MB,M'B'}$, illustrated in Fig. 10. Here we follow Ref. [34] in order to use the parameters determined in the $\Delta$ (1232) region as the starting parameters in our fits. For the $v^s$ and $v^u$ terms of Fig. 10, we include at each meson-baryon-baryon vertex a form factor of the following form

$$F(\vec{k}, \Lambda) = \frac{\vec{k}^2}{(\vec{k}^2 + \Lambda^2)^2}$$

with $\vec{k}$ being the meson momentum. For the meson-meson-meson vertex of $v^t$ of Fig. 10, the form Eq. (167) is also used with $\vec{k}$ being the momentum of the exchanged meson. For the contact term $v^c$, we regularize it by $F(\vec{k}, \Lambda) F(\vec{k}', \Lambda')$.

With the non-resonant amplitudes generated from solving Eq. (135), the resonant amplitude $t_{MB,M'B'}^R$ Eq. (127) then depends on the bare mass $M^0_N$, and the bare $N^* \rightarrow MB$ vertex functions. As discussed in Ref. [28], these bare $N^*$ parameters can be taken from a hadron structure calculation which does not include coupling with meson-baryon continuum states or meson-exchange quark interactions. We use the following parameterization,

$$\Gamma_{N^*,MB(LS)}(k) = \frac{1}{(2\pi)^{3/2}} \sqrt{\frac{1}{m_N}} C_{N^*,MB(LS)} \left( \frac{\Lambda^2_{N^*,MB(LS)}}{\Lambda^2_{N^*,MB(LS)} + (k - k_R)^2} \right)^{(2+L/2)} \left( \frac{k}{m_\pi} \right)^L$$

where $L$ and $S$ are the orbital angular momentum and the total spin of the $MB$ system, respectively. The above parameterization accounts for the threshold $k^L$ dependence and the right power $(2 + L/2)$ such that the integration for calculating the dressed vertex Eq. (130)-(131) is finite.

The partial-wave quantum numbers for the considered channels are listed in Table I. The numerical methods for handling the moving singularities due to the $\pi \pi N$ cuts in $Z_{MB,M'B'}^{(E)}$ (Fig. 15) in solving Eq. (135) are explained in detail in Ref [28]. To get the $\pi N$
Elastic scattering amplitudes, we can use either the method of contour rotation by solving the equations on the complex momentum axis $k = ke^{-i\theta}$ with $\theta > 0$ or the Spline-function method developed in Refs. [50, 51] and explained in detail in Ref. [28]. We perform the calculations using these two very different methods and they agree within less than 1%. When $Z_{MB,M'B'}^{(E)}$ is neglected, Eq. (135) can be solved by the standard subtraction method since the resonant propagators, Eqs. (132), for unstable particle channels $\pi\Delta$, $\rho N$, and $\sigma N$ are free of singularity on the real momentum axis. A code for this simplified case has also been developed to confirm the results from using the other two methods.

The method of contour rotation becomes difficult at high $E$ since the required rotation angle $\theta$ is very small. The Spline function method has no such limitation and we can perform calculations at $W > 1.9$ GeV without any difficulty. Typically, 24 and 32 mesh points are needed to get convergent solutions of the coupled-channel integral equation (135). Such mesh points are also needed to get stable integrations in evaluating the dressed resonance quantities Eqs. (129)-(131).

The parameters associated with $Z_{MB,M'B'}^{(E)}$ of Eq. (136) are completely determined from fitting the $\pi\pi$ phase shifts in Refs. [34] and [48]. Thus the considered model has the following parameters: (a) the coupling constants associated with the Lagrangians, (b) the cutoff $\Lambda$ for each vertex of $v_{MB,M'B'}$ (Fig. 10), (c) the coupling strength $C_{N^*,MB(LS)}$ and range $k_R$ and $\Lambda_{N^*,MB(LS)}$ of the bare $N^* \to MB$ vertex Eq. (168), and (d) the bare mass $M_{N^*}^{0}$ of each $N^*$ state. We determine these by fitting the $\pi N$ scattering data.

The fitting procedure is as follows. We first perform fits to the $\pi N$ scattering data up to about 1.4 GeV and including only one bare state, the $\Delta$ (1232) resonance. In these fits, the starting coupling constant parameters of $v_{MB,M'B'}$ are taken from the previous studies of $\pi N$ and $NN$ scattering, which are also given in Ref. [28]. Except the $\pi NN$ coupling constant $f_{\pi NN}$ all coupling constants and the cutoff parameters are allowed to vary in the $\chi^2$-fit to the $\pi N$ data. The coupled-channel effects can shift the coupling constants greatly from their starting values. We try to minimize these shifts by allowing the cutoff parameters to vary in a very wide range 500 MeV $< \Lambda < 2000$ MeV. Some signs of coupling constants, which could not be fixed by the previous works [53], are also allowed to change. We then use the parameters from these fits at low energies as the starting ones to fit the amplitudes up to 2 GeV by also adjusting the resonance parameters, $M_{N^*}^{0}$,
We thus start the fits including only the bare states which generate the lowest and well-established $N^*$ resonance in each partial wave. The second higher mass bare state is then included when a good fit can not be achieved. We also impose the condition that if the resulting $M_{N^*}^0$ is too high $> 2.5$ GeV, we remove such a bare state in the fit. This is due to the consideration that the interactions due to such a heavy bare $N^*$ state could be just the separable representation of some non-resonant mechanisms which should be
included in \( v_{MB,M'B'} \). In some partial waves the quality of the fits is not very sensitive to the \( N^* \) couplings to \( \pi \Delta, \rho N, \) and \( \sigma N \). But the freedom of varying these coupling parameters is needed to achieve good fits.

It is rather difficult to fit all partial waves simultaneously because the number of resonance parameters to be determined is very large. We proceed as follows. We first fit only 3 or 4 partial waves which have well established resonant states, and whose amplitudes have an involved energy dependence. These are the \( S_{11}, P_{11}, S_{31} \) and \( P_{33} \) partial waves. These fits are aimed at identifying the possible ranges of the parameters associated with \( v_{MB,M'B'} \). We then gradually extend the fits to include more partial waves. For some cases, the fits can be reached easily by simply adjusting the bare \( N^* \) parameters. But it often requires some adjustments of the non-resonant parameters to obtain new fits. This procedure has to be repeated many times to explore the parameter space as much as we can. We use the fitting code MINUIT and the parallel computation facilities at NERSC in US and the Barcelona Supercomputing Center in Spain.

The most uncertain part of the fitting is to handle the large number of parameters associated with the bare \( N^* \) states. Here the use of the empirical partial-wave amplitudes from SAID is an essential step in the fit. It allows us to locate the ranges of the \( N^* \) parameters partial-wave by partial-wave for a given set of the parameters for the non-resonant \( v_{MB,M'B'} \). Even with this, the information is far from complete for pinning down the \( N^* \) parameters. Perhaps the \( N^* \) parameters associated with the \( \pi N \) state are reasonably well determined in this fit to the \( \pi N \) scattering data. The parameters associated with \( \eta N, \pi \Delta, \rho N \) and \( \sigma N \) can only be better determined by also fitting to the data of \( \pi N \to \eta N \) and \( \pi N \to \pi \pi N \) reactions. This will be pursued in our future calculations.

It is useful to note here that the leading-order effect due to \( Z^{(E)} \) of the meson-baryon interaction Eq. (136) on \( \pi N \) elastic scattering is

\[
\delta v_{\pi N,\pi N} = \sum_{MB,M'B'=\pi \Delta,\rho N,\sigma N} v_{\pi N,MB} G_{MB}(E) Z^{(E)}_{MB,M'B'} G_{M'B'}(E) v_{M'B',\pi N} .
\]

We have found by explicit numerical calculations that \( \delta v_{\pi N,\pi N} \) is much weaker than \( v_{\pi N,\pi N} \) and hence the coupled channel effects due to \( Z^{(E)}_{MB,M'B'} \) on \( \pi N \) elastic scattering amplitude are weak. One example obtained from our model is shown in Table II. Thus we first perform the fits without including \( Z^{(E)} \) term to speed up the computation. We
then refine the parameters by including this term in the fits.

TABLE II: The effect of $Z_{MB,M'B'}^{(E)}$ on the $πN$ scattering amplitudes $t_{πN,πN}$ from solving Eq. (135) at $E = 1.7$ GeV. The normalization is $t_{πN,πN} = (e^{2iδ_{πN}} - 1)/(2i)$, where $δ_{πN}$ is the $πN$ scattering phase shift which could be complex at energies above the $π$ production threshold.

We first locate the range of the parameters by fitting the empirical $πN$ scattering amplitude of SAID [20]. We then check and refine the resulting parameters by directly comparing our predictions with the original $πN$ scattering data.

Our fits to the empirical amplitudes of SAID [20] are given in Figs. 19-20 and Figs. 21-22 for the $T = 1/2$ and $T = 3/2$ partial waves, respectively. The resulting parameters are presented in Appendix D. The parameters associated with the non-resonant interactions, $v_{MB,M'B'}$ with $MB, M'B' = πN, ηN, πΔ, ρN, σN$, are given in Table IX for the coupling constants of the starting Lagrangian and Table X for the cutoffs of the form factors defined by Eq. (167). The resulting bare $N^*$ parameters are listed in Tables XI-XIII.

From Figs. 19-22, one can see that the empirical $πN$ amplitudes can be fitted very
FIG. 19: Real parts of the calculated $\pi N$ partial wave amplitudes (Eq. (126)) of isospin $T = 1/2$ are compared with the energy independent solutions of Ref. [20].

well. The most significant discrepancies are in the imaginary part of $S_{31}$ in Fig.22. The agreement is also poor for the $F_{17}$ in Fig.19-20 and $D_{35}$ in Figs.21-22, but there are rather large errors in the data. Our parameters are therefore checked by directly comparing our predictions with the data of differential cross sections $d\sigma/d\Omega$ and target polarization asymmetry $P$ of elastic $\pi^\pm p \to \pi^\pm p$ and charge-exchange $\pi^- p \to \pi^0 n$ processes. Our results (solid red curves) are shown in Figs.23-27. Clearly, our model is rather consistent with the available data, and are close to the results (dashed blue curves) calculated from the SAID’s amplitudes. Thus our model is justified despite the differences with the SAID’s amplitudes seen in Fig.19-22.

It will be important to further refine our parameters by fitting the data of other $\pi N$ scattering observables, such as the recoil polarization and double polarization. Hopefully, such data can be obtained from the new hadron facilities at JPARC in Japan.

Our model is further checked by examining our predictions of the total cross sections $\sigma^{tot}$ which can be calculated from the forward elastic scattering amplitudes by using the optical theorem. The total elastic scattering cross sections $\sigma^{el}$ can be calculated from the
IV DYNAMICAL MODEL OF MESON PRODUCTION REACTIONS

FIG. 22: Imaginary parts of the calculated \( \pi N \) partial wave amplitudes (Eq. (126)) of isospin \( T = 3/2 \) are compared with the energy independent solutions of Ref. [20].
IV DYNAMICAL MODEL OF MESON PRODUCTION REACTIONS

FIG. 23: Differential cross section for several different center of mass energies. Solid red curve corresponds to our model while blue dashed lines correspond to the SP06 solution of SAID [20]. All data have been obtained through the SAID online applications. Ref. [20].

contribution in the center of mass frame

\[
\sigma_{\pi\Delta}(E) = \int_{m_N+m_s}^{E-m_\pi} dM_{\pi N} \frac{M_{\pi N}}{E_{\Delta}(k)} \frac{\Gamma_{\pi\Delta}(k, E)/(2\pi)}{|E - E_{\pi}(k) - E_{\Delta}(k) - \Sigma_{\pi\Delta}(k, E)|^2} \sigma_{\pi N \rightarrow \pi\Delta}(k, E) \tag{173}
\]

where \( k \) is defined by \( M_{\pi N} = E_{\pi}(k) + E_N(k) \), \( E_{\pi N}(k) = [M_{\pi N}^2 + k^2]^{1/2} \), \( \Sigma_{\pi\Delta}(k, E) \) is defined in Eq.(162), \( \Gamma_{\pi\Delta}(k, E) = -2Im(\Sigma_{\pi\Delta}(k, E)) \), and

\[
\sigma_{\pi N \rightarrow \pi\Delta}(k, E) = 4\pi \rho_{\pi N}(k_0) \rho_{\pi\Delta}(k) \sum_{L'S',LS,J} \frac{2J + 1}{(2S_N + 1)(2S_\pi + 1)} |T_{L'S',\pi\Delta,LS,\pi N}^J(k, k_0; E)|^2 \tag{174}
\]

where \( k_0 \) is defined by \( E = E_{\pi}(k_0) + E_N(k_0) \) and \( \rho_{ab}(k) = \pi k E_a(k) E_b(k) / E \). The amplitude \( T_{L'S',\pi\Delta,LS,\pi N}^J(k, k_0; E) \) is the partial-wave solution of Eq.(126). The corresponding expressions for the unstable channels \( \rho N \) and \( \sigma N \) can be obtained from Eqs. (173)-(174) by changing the channel labels.

The predicted \( \sigma^{tot} \) (solid curves) along with the resulting total elastic scattering cross sections \( \sigma^{el} \) compared with the data of \( \pi^+ p \) reaction are shown in Fig. 28. Clearly, the
model can account for the data very well within the experimental errors. Here only the $T = \frac{3}{2}$ partial waves are relevant. Equally good agreement with the data for $\pi^- p$ reaction are shown in the left side of Fig. 29. In the right side, we show how the contributions from each channel add up to get the total cross sections. The comparison of the contribution from $\eta N$ channel with the data is shown in Fig. 30. It is possible to improve the fit to this data by adjusting $N^* \rightarrow \eta N$ parameters. But this can be done correctly only when the differential cross section data of $\pi N \rightarrow \eta N$ are included in the fit.

The contributions from $\pi \Delta$, $\rho N$ and $\sigma N$ intermediate states to the $\pi^- p \rightarrow \pi \pi N$ total cross sections calculated from our model can be seen in the right side of Fig. 29. These predictions remain to be verified by the future experiments. The existing $\pi N \rightarrow \pi \pi N$ data are not sufficient for extracting model independently the contributions from each unstable channel.

FIG. 24: Differential cross section for several different center of mass energies. Similar description as Fig. 23. All data have been obtained through the SAID online applications. Ref. [20].
FIG. 25: Target polarization asymmetry, $P$, for several different center of mass energies. Similar description as Fig. 23. All data have been obtained through the SAID online applications. Ref. [20].

The results shown in Figs. 28-30 indicate that our parameters are consistent with the total cross section data.

F. Pion electroproduction

We perform a dynamical coupled-channel analysis of $p(e, e'\pi)N$ data in the region of $E \leq 1.6$ GeV and $Q^2 \leq 1.45$ (GeV/c)$^2$. This model is an extension of the analysis [30] of pion photoproduction reactions. With the hadronic parameters of the employed dynamical coupled-channels model determined in analyzing the $\pi N$ reaction data [29, 55], the only freedom in analyzing the electromagnetic meson production reactions is the electromagnetic coupling parameters of the model. If the parameters listed in Ref. [28] are used to calculate the non-resonant interaction, the only parameters to be determined from the data of pion electroproduction reactions are the bare $\gamma^*N \rightarrow N^*$ helicity amplitudes for the lowest $N^*$ states in $P_{33}$, $P_{11}$, $S_{11}$ and $D_{13}$ partial waves. Such a highly constrained
The resonant amplitude is given by replacing initial meson-baryon state in Eq. (127) with $\gamma^*N$,

$$t^{R,j}_{LSN\pi N,\lambda,\lambda N}(k, q, E, Q^2) = \sum_{N^*_j, N^*_{j'}} [\tilde{\Gamma}^{j}_{N^*_j,LSN\pi N}(k, E)]^* D_{i,j}(E) \tilde{\Gamma}^{j}_{N^*_{j'},\lambda,\lambda N}(q, E, Q^2),$$

(175)

where $S_N = 1/2$ is the nucleon spin, $E = \omega + E_N(q)$ is the invariant mass of the $\gamma^*N$ system. The dressed $N^* \rightarrow \pi N$ vertex $\tilde{\Gamma}^{j}_{N^*_j,LSN\pi N}(k, E)$ and $N^*$ propagator $D_{i,j}(E)$ have been determined and given explicitly in Ref. [30]. The dressed $\gamma^*N \rightarrow N^*$ vertex function is

$$\tilde{\Gamma}^{j}_{N^*\lambda,\lambda N}(q, E, Q^2) = \Gamma^{j}_{N^*\lambda,\lambda N}(q, Q^2)$$
FIG. 27: Target polarization asymmetry, $P$, for several different center of mass energies. Description as in Fig. 23. All data have been obtained through the SAID online applications. Ref. [20].

FIG. 28: The predicted total cross sections of the $\pi^+ p \rightarrow X$ (solid curve) and $\pi^+ p \rightarrow \pi^+ p$ (dashed curve) reactions are compared with the data. Squares and triangles are the corresponding data from Ref. [24].
FIG. 29: Left: The predicted total cross sections of the \( \pi^- p \to X \) (solid curve) and \( \pi^- p \to \pi^- p + \pi^0 n \) (dashed curve) reactions are compared with the data. Open squares are the data on \( \pi^- p \to X \) from Ref. [24], open triangles are obtained by adding the \( \pi^- p \to \pi^- p \) and \( \pi^- p \to \pi^0 n \) data obtained from Ref. [24] and SAID database [54] respectively. Right: Show how the predicted contributions from each channel are added up to the predicted total cross sections of the \( \pi^- p \to X \).

We define the bare \( \gamma^* N \to N^* \) vertex functions \( \Gamma^{J^*}_{N^*\lambda\gamma\lambda_N}(q, Q^2) \) of Eq. (176). We parameterize these functions as

\[
\Gamma^{J^*}_{N^*\lambda\gamma\lambda_N}(q, Q^2) = \frac{1}{(2\pi)^{3/2}} \sqrt{\frac{m_N}{E_N(q)}} \sqrt{\frac{q_R}{|q_0|}} G_{\lambda}(N^*, Q^2) \delta_{\lambda, \lambda^- \lambda_N},
\]

(177)

where \( q_R \) and \( q_0 \) are defined by \( M_{N^*} = q_R + E_N(q_R) \) with \( N^* \) mass and \( E = q_0 + E_N(q_0) \), respectively, and

\[
G_{\lambda}(N^*, Q^2) = \begin{cases} 
A_{\lambda}(N^*, Q^2), & \text{for transverse photon,} \\
S_{\lambda}(N^*, Q^2), & \text{for longitudinal photon.}
\end{cases}
\]

(178, 179)

We also cast the helicity amplitudes of the dressed vertex Eq. (176) into the form of
IV DYNAMICAL MODEL OF MESON PRODUCTION REACTIONS

FIG. 30: The predicted total cross sections of $\pi p \rightarrow \eta p$ reaction are compared with the data [74, 75].

Eq. (177) with dressed helicity amplitudes

$$\bar{A}_\lambda(N^*, Q^2) = A_\lambda(N^*, Q^2) + A_{\lambda}^{m.c.}(N^*, Q^2),$$

$$\bar{S}_\lambda(N^*, Q^2) = S_\lambda(N^*, Q^2) + S_{\lambda}^{m.c.}(N^*, Q^2),$$

where $A_{\lambda}^{m.c.}(N^*, Q^2)$ and $S_{\lambda}^{m.c.}(N^*, Q^2)$ are due to the meson cloud effect defined by the second term of Eq. (176). Here we emphasize these helicity amplitudes are defined at the real mass of $N^*$ in order to discuss the difference between bare amplitudes and dressed amplitudes due to the shift by meson cloud effects. Helicity amplitudes in terms of the residue of resonance poles on complex energy plane will be given and discussed in Section V.

We first try to fix the bare helicity amplitudes by fitting to the data of $\sigma_T + \epsilon \sigma_L$, $\sigma_{LT}$, and $\sigma_{TT}$ of $p(e, e'\pi^0)p$ in Ref.[56] which covers almost all $(E, Q^2)$ region we are considering (see Table.III). The formula for calculating $\sigma_\alpha$ from the amplitudes are given in Ref. [44]. In a purely phenomenological approach, we first vary all of the helicity amplitudes of 16 bare $N^*$ states, considered in analyzing the $\pi N \rightarrow \pi N, \pi\pi N$ data [29, 55], in the fits to the data. It turns out that only the helicity amplitudes of the first $N^*$ states in $S_{11}$, $P_{11}$, $P_{33}$ and $D_{13}$ are relevant in the considered $E \leq 1.6$ GeV. Thus in this paper only the bare helicity amplitudes associated with those four bare $N^*$ states (total 10 parameters) are varied in the fit and other bare helicity amplitudes are set to zero. The numerical fit
FIG. 31: Fit to \( p(e, e'\pi^0)p \) structure functions at \( Q^2 = 0.4 \text{ (GeV}/c)^2 \). Here \( \theta \equiv \theta^*_\pi \). The solid curves are the results of Fit1, the dashed curves are of Fit2, and the dotted curves are of Fit3. (See text for the description of each fit.) The data are taken from Refs. [56, 59].

is performed at each \( Q^2 \) independently, using the MINUIT library.

The results of the fits are the solid curves in the top three rows of Figs. 31-33. Clearly our results from this fit agree with the data well. We obtain similar quality of fits to the data of Ref. [56] at other \( Q^2 \) values listed in Table. III. We have also used the magnetic \( M1 \) form factor of \( \gamma^*N \to \Delta(1232) \) extracted from previous analyses as data for fitting. The results are shown in Fig. 34. We refer the results of this fit to as “Fit1”.

In Fig. 35, we present the \( G^*_M, G^*_E, \) and \( G^*_C \) form factors of \( \gamma^*N \to \Delta(1232) \) transition obtained from Fit1 (solid points). In the same figure, we also show the meson cloud effect in the form factors. Within our model, it has a significant contribution at low \( Q^2 \), but rapidly decreases as \( Q^2 \) increases, particularly for \( G^*_E \) and \( G^*_C \). These results are similar to the previous findings [45, 57].

The helicity amplitudes of \( S_{11}, P_{11}, \) and \( D_{13} \) resulting from Fit1 are shown in Fig. 36. The solid circles are the absolute magnitude of the dressed helicity amplitudes (180) and (181). The errors there are assigned by MIGRAD in the MINUIT library. More
FIG. 32: Fit to \( p(e, e'\pi^0)p \) structure functions at \( Q^2 = 0.9 \text{ (GeV/c)}^2 \). Here \( \theta \equiv \theta_x^* \). The data are taken from Ref. [56].

detailed analysis of the errors is perhaps needed, but will not be addressed here. The meson cloud effect (dashed curves), as defined by \( A_{\text{m.c.}}^\lambda \) and \( S_{\text{m.c.}}^\lambda \) of Eqs. (180) and (181) and calculated from the second term of Eq. (176), are the necessary consequence of the unitarity conditions. They do not include the bare helicity term determined here and are already fixed in the photoproduction analysis [30]. Within our model (and within Fit1), the meson cloud contribution is relatively small in \( S_{11} \) and \( A_{1/2} \) of \( D_{13} \) even in the low \( Q^2 \) region.

Here we note that our helicity amplitudes defined in Eqs. (180) and (181) are different from the commonly used convention, say \( A_{\text{cnv}}^\lambda \) and \( S_{\text{cnv}}^\lambda \), which are obtained from the imaginary part of the \( \gamma^*N \rightarrow \pi N \) multipole amplitudes [58]. This definition leads to helicity amplitudes which are real, while our dressed amplitudes are complex. It was shown in Ref. [45] that for the \( \Delta(1232) \) resonance our dressed helicity amplitudes (180) and (181) can be reduced to \( A_{\text{cnv}}^\lambda \) and \( S_{\text{cnv}}^\lambda \), if we replace the Green function \( G_{\pi N} \) with its principal value in all loop integrals appearing in the calculation. However, such reduction is not so trivial for higher resonance states because the unstable \( \pi \Delta, \rho N, \sigma N \) channels open, and thus the direct comparison of the helicity amplitudes from other analyses
FIG. 33: Fit to $p(e, e'\pi^0)p$ structure functions at $Q^2 = 1.45 \, (\text{GeV}/c)^2$. Here $\theta \equiv \theta_\pi^*$. The data are taken from Ref. [56].

becomes unclear. We will again discuss the complex helicity amplitudes in terms of resonance poles and residues in Section V.

At $Q^2 = 0.4 \, (\text{GeV}/c)^2$, the data of all structure functions both for $p(e, e'\pi^0)p$ and $p(e, e'\pi^+)n$ are available as seen in Table. III. To see the sensitivity of the resulting helicity amplitudes to the amount of the data included in the fits, we further carry out two fits at this $Q^2$, referred to as Fit2 and Fit3, respectively. Fit2 (Fit3) further includes the data of Refs. [59–61] (Ref. [59]) in the fit in addition to those of Ref. [56] which are used in Fit1. This means that Fit2 includes all available data both from $p(e, e'\pi^0)p$ and $p(e, e'\pi^+)n$, whereas Fit3 includes the same data but from $p(e, e'\pi^0)p$ only. The results of each fit are the dashed and dotted curves in Fig. 31 for $p(e, e'\pi^0)p$ and Fig. 37 for $p(e, e'\pi^+)n$, respectively.

The resulting bare helicity amplitudes are listed in the third (Fit2) and fourth (Fit3) columns of Table II and compare with that from Fit1. The corresponding change in the $\gamma N \rightarrow \Delta(1232)$ form factors and the dressed helicity amplitudes are also shown as open circles and triangles in Figs. 35 and 36. A significant change among the three different fits is observed in most of the results except $G_M^\pi$ in $P_{33}$. This indicates that fitting the
IV DYNAMICAL MODEL OF MESON PRODUCTION REACTIONS

FIG. 34: $G_M^*$ normalized by the dipole factor $G_D = [1 + Q^2/0.71(\text{GeV/c})^2]^{-2}$. The solid black circles at $Q^2 > 0$ are our fit to the values extracted from previous analyses (those values are taken from Ref. [30]). The triangle at $Q^2 = 0$ is from our photoproduction analysis [30].

FIG. 35: The $\gamma^*N \to \Delta(1232)$ form factors. Solid points are from Fit1; dashed curves are the meson cloud contribution. Open circles and triangles at $Q^2 = 0.4$ (GeV/c)$^2$ are from Fit2 and Fit3, respectively. The three points are almost overlapped in $G_M^*$. The solid point at $Q^2 = 0$ is obtained from the photoproduction reaction analysis in Ref. [30].

data listed in Table III are far from sufficient to pin down the $\gamma^*N \to N^*$ transition form factors up to $Q^2 = 1.45$ (GeV/c)$^2$. It clearly indicates the importance of obtaining data from complete or over-complete measurements of most, if not all, of the independent $p(e, e'\pi)N$ polarization observables. Such measurements were made by Kelly et al. [62] in the $\Delta$ (1232) region and will be performed at JLab for wide ranges of $E$ and $Q^2$ in the next few years [5].

It has been seen in Fig. 37 that all of our current fits underestimate $\sigma_T$ of $p(e, e'\pi^+)n$ at

Table IV: Ambiguity of resulting bare helicity amplitudes [the results are at \( Q^2 = 0.4 \) (GeV/c)^2]. The errors are assigned by MIGRAD in the MINUIT library.
**IV DYNAMICAL MODEL OF MESON PRODUCTION REACTIONS**

FIG. 36: Extracted helicity amplitudes for $S_{11}$ at $E = 1535$ MeV (upper panels), $P_{11}$ at $E = 1440$ MeV (middle panels), and $D_{13}$ at $E = 1520$ MeV (lower panels). The meaning of each point and curve is same as in Fig. 35.

forward angles. We find that this can be improved by further varying the $S_{31}$ and $P_{13}$ bare helicity amplitudes within their reasonable range. In Fig. 38, the results with the nonzero $S_{31}$ and $P_{13}$ bare helicity amplitudes (solid curves) are compared with the results without varying those amplitudes (dashed curves). The resulting values of the bare helicity amplitudes are $(A_{1/2}^{S_{31}}, S_{1/2}^{S_{31}}) = (121.6, 59.6)$ and $(A_{3/2}^{P_{13}}, A_{1/2}^{P_{13}}, S_{1/2}^{P_{13}}) = (-73.2, -42.9, 41.5)$. The parameters of Fit2 are used for $S_{11}$, $P_{11}$, $P_{33}$, and $D_{13}$ in both curves. In the figure we have just shown the results at $E \sim 1.3$ GeV. We confirm that the same consequence is obtained also at other $E$, and find that the $P_{13}$ ($S_{31}$) has contributions mainly at low (high) $E$. We also find that the inclusion of the bare $S_{31}$ and $P_{13}$ helicity amplitudes does not change other structure functions than $\sigma_T$ of $p(e, e'\pi^+)n$ (at most, most of the change is within the error). This indicates that those two helicity amplitudes are rather relevant to $p(e, e'\pi^+)n$, but not to $p(e, e'\pi^0)p$. As shown in Table III, however, no enough data is currently available for $p(e, e'\pi^0)n$ above $Q^2 = 0.4$ (GeV/c)$^2$. The data both of the $p(e, e'\pi^0)p$ and $p(e, e'\pi^+)n$ at same $Q^2$ values are desirable to pin down the $Q^2$ dependence.
FIG. 37: Structure functions of \( p(e, e'\pi^+)n \) at \( Q^2 = 0.4 \) (GeV/c)^2. Here \( \theta \equiv \theta_{LT}' \). The solid curves are the results of Fit1, the dashed curves are of Fit2, and the dotted curves are of Fit3. (See text for the description of each fit.) As for the \( \sigma_{LT} \), results at \( E = 1.14, 1.22, 1.3, 1.38, 1.5, 1.58 \) GeV (from left to right of the bottom row) are shown, in which the data are available. The data in the figure are taken from Ref. [60, 61].

of the \( S_{31} \) and \( P_{13} \) helicity amplitudes.

We now turn to show the coupled-channels effect. In Fig. 39, we see that when only the \( \pi N \) intermediate state is kept in the \( M' B' \) summation of the non-resonant amplitude [Eq. (135)] and the dressed \( \gamma^* N \to N^* \) vertices [Eq. (176)], the predicted total transverse and longitudinal cross sections \( \sigma_T \) and \( \sigma_L \) of \( p(e, e'\pi^0)p \) are changed from the solid to dashed curves. This corresponds to only examining the coupled-channels effect on the electromagnetic (\( Q^2 \)-dependent) part in the \( \gamma^* N \to \pi N \) amplitude. All coupled-channels effects on the non-electromagnetic interactions are kept in the calculations. We find that the coupled-channels effect tends to decrease when \( Q^2 \) increases. This is rather clearly seen in \( \sigma_T \). In particular, the coupled-channels effect on \( \sigma_T \) at high \( E \sim 1.5 \) GeV is small (10-20%) already at \( Q^2 = 0.4 \) (GeV/c)^2. (The effect is about 30-40% at \( Q^2 = 0 \) [30].) This is understood as follows. In Eq. (175) we can further split the resonant amplitude \( t^R \) as \( t^R = t^R_{\text{bare}} + t^R_{\text{m.c.}} \), where \( t^R_{\text{bare}} \) and \( t^R_{\text{m.c.}} \) are the same as \( t^R \) but replacing
FIG. 38: Contribution of the $S_{31}$ and $P_{13}$ helicity amplitudes at $Q^2 = 0.4$ (GeV/c)$^2$. The left (right) panels are the structure functions of $p(e, e'\pi^0)p$ [$p(e, e'\pi^+)n$] reaction at $E = 1.3$ GeV ($E = 1.29$ GeV). Solid (dashed) curves are the results with (without) nonzero $S_{31}$ and $P_{13}$ bare helicity amplitudes. The parameters of Fit2 are used for the $S_{11}$, $P_{11}$, $P_{33}$, and $D_{13}$ helicity amplitudes in both curves. The data are from Refs. [56, 59–61].

$\bar{\Gamma}_{N\ast,\lambda_N,\lambda_N}$ with its bare part $\Gamma_{N\ast,\lambda_N,\lambda_N}$ and meson cloud part [the second term of Eq. (176)], respectively. The coupled-channels effect shown in Fig. 39 comes from $t_{LS\pi\pi,\lambda,\lambda_N}^R$ and $t_{m.c.}^R$. We have found that the relative importance of the coupled-channels effect in each part remains the same for increasing $Q^2$. However, the contribution of non-resonant mechanisms both on $t_{LS\pi\pi,\lambda,\lambda_N}^R$ and $t_{m.c.}^R$ to the structure functions decreases for higher $Q^2$ compared with $t_{bare}^R$. This explains the smaller coupled-channels effect compared with the photoproduction reactions [30]. The decreasing non-resonant interaction at higher $Q^2$ is due to its long range nature, thus indicating that higher $Q^2$ reactions provide a
clearer probe of $N^*$. We obtain similar results also for $p(e, e' \pi^+)n$.

It is noted, however, that the above argument does not mean coupled-channels effect is negligible in the full $\gamma^* N \rightarrow \pi N$ reaction process. In the above analysis we kept the coupled-channels effect on the hadronic non-resonant amplitudes, the strong $N^*$ vertices, and the $N^*$ self-energy, which are $Q^2$-independent and remain important irrespective of $Q^2$. We have found in the previous analyses [29, 55] that the coupled-channels effect on them is significant in all energy region up to $E = 2$ GeV.

In Fig. 40, we show the coupled-channels effect on the five-fold differential cross section. The coupled-channels effects are significant at low $E$, whereas they are small at high $E$. This is consistent with the above discussions because the five-fold differential cross sections are dominated by $\sigma_T$. Here we also see that our full results (solid curves) are in good agreement with the original data, although we performed the fits by using the structure function data listed in Table III.

FIG. 39: Coupled-channels effect on the integrated structure functions $\sigma_T(E)$ and $\sigma_L(E)$ for $Q^2 = 0.4, 0.9, 1.45$ (GeV/c)$^2$ for $p(e, e' \pi^0)p$ reactions. The solid curves are the full results calculated with the bare helicity amplitudes of Fit1. The dashed curves are the same as solid curves but only the $\pi N$ loop is taken in the $M'B'$ summation in Eqs. (135) and (176).
FIG. 40: Coupled-channels effect on the five-fold differential cross sections $\Gamma^{-1}_{\gamma}[d\sigma/(dE'd\Omega_{e'}d\Omega_{e''}d\Omega_{\pi}')]$ of $p(e,e'\pi^0)p$ (upper panels) and $p(e,e'\pi^+)n$ (lower panels) at $Q^2 = 0.4$ (GeV/c)^2. Here $\theta \equiv \theta^*_{\pi}$ and $\phi \equiv \phi^*_{\pi}$. The solid curves are the full results calculated with the bare helicity amplitudes of Fit1. The dashed curves are the same as the solid curves but only the $\pi N$ loop is taken in the $M'B'$ summation in Eqs. (135) and (176). The data are taken from Ref. [63].
V. RESULTS AND DISCUSSIONS

A. Analytic continuation and pole positions

To extract the information of resonance poles from the dynamical coupled channel model described in Section IV, it is necessary to choose the proper integral path for analytic continuation. We need to choose the contours $C_{MB}$ and $C_3$ appropriately to solve the coupled channel problem for $E$ on various possible unphysical sheets of the Riemann surface as described in Section II. This requires careful examinations of the locations of the on-shell momentum of each propagator $G_{MB}(k, E)$ and the $\pi\pi N$ cut in the self energies, such as $\Sigma_{\pi\Delta}(k, E)$ of Eq. (162), of the unstable particle channels.

![Diagram](image)

**FIG. 41:** Singularities and integral path on the complex momentum plane at $E = 1357 - 76i$ MeV. Red crosses are singularities of meson-baryon propagator given by Eqs. (182) and (183). Green line and square (blue line and circle) are $\pi\pi N$ cut and a branch point for the selfenergy of $\pi\Delta$ by Eq. (185) ($\sigma N$ and $\rho N$ by Eq. (185)). Red line shows an integral path.

Here we present one example, the case for a pole on $P_{11}$ partial wave amplitude which corresponds to $N^*(1440)$. In Fig. 41, the singularities of meson-baryon propagator on complex momentum plane at $E = 1357 - 76i$ MeV, that turns out to be the pole position on complex energy plane as a result of the pole search, are shown by red crosses. Each singularity of meson-baryon propagator is obtained by solving

$$E - E_M(p) - E_B(p) = 0,$$

(182)
for stable particle channels $MB = \pi N, \eta N$, and
\[
E - E_M(p) - E_B(p) - \Sigma_{MB}(p, E) = 0,
\]
(183)

for unstable particle channels $MB = \pi \Delta, \rho N, \sigma N$. The left-hand side of these two equations are the denominator of propagator $G_{MB}(p, E)$ given by Eq. (160) and (161). The branch point of $\pi \pi N$ cut in the self energy $\Sigma_{\pi \Delta}, \Sigma_{\sigma N}$ and $\Sigma_{\rho N}$ are given as
\[
E = E_\pi(p_0) + [(m_\pi + m_N)^2 + p^2_0]^{1/2} \quad \text{for} \quad \pi \Delta,
\]
(184)
\[
E = E_N(p_0) + [(2m_\pi)^2 + p^2_0]^{1/2} \quad \text{for} \quad \rho N \quad \text{and} \quad \sigma N,
\]
(185)

and they are shown in Fig. 41 by green line and square for $\pi \Delta$ and by blue line and circle for $\rho N$ and $\sigma N$. Actually, the singularities for each meson-baryon channel are on the different momentum plane and we can choose a different integral path for each channel independently, which means we can choose a different Riemann sheet of each channel. Here, for simplicity, we illustrate all singularities on the single complex plane and take the same path for every channel in Fig. 41, where the path is shown by red line. The real part of the considered energy is 1357 MeV, that is above the threshold energies for $\pi N$ and $\pi \pi N$, and below that for $\eta N, \sigma N$ and $\rho N$. So the unphysical sheet for $\pi N$ and $\pi \pi N$ is the nearest sheet from the physical region and we choose the path below the singularities of $\pi N$ and $\pi \pi N$ for analytic continuation to the unphysical sheet of them. On the other hand, the physical sheet for $\eta N, \sigma N$ and $\rho N$ is the nearest sheet from the physical region and we take the path above the singularity of $\eta N$. Singularities of $\sigma N$ and $\rho N$ are on the upper half of complex momentum plane, which means we look at the physical sheet for such channels by the considered path. We choose the unphysical sheet of $\pi \Delta$ in Fig. 41, though the both of unphysical and physical sheets for $\pi \Delta$ are close to the physical region because the $\pi \Delta$ threshold is just close to 1357 MeV. Thus we can calculate the amplitude at the complex energy $E = 1357 - 76i$ MeV.

We search for poles of the total amplitudes from finding the zeros of the determinant of $D^{-1}(E)$ defined by Eq. (128). Here we use the well-established Newton iteration method in Appendix A. We have performed searches in the $(m_\pi + m_N) \leq \text{Re}(E) \leq 2000$ MeV and $-\text{Im}(E) \leq 350$ MeV region within which PDG’s 3- and 4-stars resonances are listed. Poles with very large widths are more difficult to locate precisely with our numerical methods and hence will not be discussed here. In Table V, the extracted resonance poles positions

**TABLE V:** The resonance pole positions $M_R$ [listed as (Re $M_R$, $-\text{Im } M_R$)] extracted from the dynamical model in the different unphysical sheets are compared with the values of 3- and 4-stars nucleon resonances listed in the PDG [24]. “—” for $P_{33}(1600)$, $P_{13}$ and $P_{31}$ indicates that no resonance pole has been found in the considered complex energy region, Re($E$) ≤ 2000 MeV and $-\text{Im}(E)$ ≤ 350 MeV.

$(M_R)$ are compared with the bare $N^*$ masses $(M^0_N)$ of our model and the 3- and 4-star values listed by PDG [24]. Like the previous works [64, 67], we only look for poles which are close to the physical region and have effects on $\pi N$ scattering observables. All of these poles are on the unphysical sheet of the $\pi N$ channel, but could be on either unphysical
(u) or physical (p) sheets of other channels considered in this analysis. We will indicate
the sheets where the identified poles are located by \((s_{\pi N}, s_{\eta N}, s_{\pi\pi N}, s_{\pi\Delta}, s_{\rho N}, s_{\pi N})\), where
\(s_{MB}\) and \(s_{\pi\pi N}\) can be \(u\) or \(p\) or \(-\) denoting no coupling to this channel. Let us remark
that the only physical sheet is the \((pppppp)\). On that sheet the full amplitude should be
analytic except for a bound state pole and a unitary cut. Any other sheet is unphysical.

With the exception of the \(P_{33}(1600)\), \(P_{13}\) and \(P_{31}\) cases, all pole positions listed by
the PDG are consistent with our results. One possible reason for not finding these poles
is that their imaginary part may be beyond the \(-\text{Im}(M_R) \leq 350\,\text{MeV}\) region where
our analytic continuation method is accurate and is covered in our searches. Another
possibility is that these resonances, if indeed exist, are perhaps due to the mechanisms
which are beyond our model, but are particularly sensitive to these partial waves. The \(P_{11}\)
pole at \(1999 - 321i\) MeV has no corresponding resonance on the PDG. The imaginary part
of this pole is so large that we might hardly compare it with the analysis of experimental
results.

![Graph](attachment:image.png)

**FIG. 42:** Trajectories of the evolution of \(P_{11}\) resonance poles A (1357, -76), B (1364, -105), C
(1820, -248) and D(1999, -321) from a bare \(N^*\) with 1763 MeV and 2037 MeV, as the couplings
of the bare \(N^*\) with the meson-baryon reaction channels are varied from zero to the full strengths
of our model.

For \(P_{11}\) channel we find four poles below 2 GeV. Two of them near 1360 MeV are close
to the \(\pi\Delta\) threshold. This finding is consistent with the earlier analysis of VPI[26] and
Cutkosky and Wang[27], and the recent analysis by the GWU/VPI[67] and Juelich[68]

TABLE VI: $P_{11}$ resonance poles extracted from three different approaches and near the Roper resonance position of PDG are compared.

groups as seen in Table VI. We find that they are on different sheets: (1357, -76) and (1346, -105) are on the unphysical and physical sheet of the $\pi\Delta$ channel, respectively.

Within our model, we can further study the dynamical origin of these two nearby poles around the $\pi\Delta$ threshold. The way the identified resonance poles evolve dynamically from their bare masses (listed in Table V) through their coupling with reaction channels can be examined by tracing the zeros of $\det[D^{-1}(E)] = \det[E - M_N^R - \sum_{MB} y_{MB} M_{MB}(E)]$ in the region $0 \leq y_{MB} \leq 1$, where $M_{MB}(E)$ is the contribution of channel $MB$ to the self energy defined by Eq. (128). Each $y_{MB}$ is varied independently to find continuous evolution paths through the various Riemann sheets on which our analytic continuation method is valid.

For the $P_{11}$ case we found the three poles are associated to one bare state as shown in Fig. 42. The poles A(1357, -76), B(1364, -105) and C(1820, -248) evolve from the same bare state with a mass of 1763 MeV. The pole D(1999, -321) corresponds to the other bare state with a mass of 2037 MeV. The poles A and B are on the physical sheet of the $\eta N$ channel and their difference occurs due to the choice of the sheet for $\pi\Delta$ channel. The green curve indicates how the bare state evolves through varying all coupling strengths except keeping $y_{\pi\Delta} = 0$, to about $Re(M_R) \sim 1400$ MeV. By further varying $y_{\pi\Delta}$ to 1 of the full model, it then splits into two trajectories; one moves to pole A on the unphysical sheet and the other to B on the physical sheet of $\pi\Delta$ channel. Our finding suggests that the number of resonance poles found from the analysis of pion-nucleon scattering amplitudes does not necessarily correspond to the number of the 'bare' states. The dynamical coupled channel induces multi-poles from a single bare state. Although a cusp-like move may be seen in the trajectory to the pole C, it is not actually a cusp but a differentiable curve. It is due to the influence of the upper resonance D.
Next, we apply the procedure for extracting residues of resonance poles developed in Section III by presenting the results for $P_{33}$, $D_{13}$ and $P_{11}$ partial waves. The extracted residues $Re^{i\phi}$, defined in Eq.(114), for $\pi N$ amplitude are compared with some of the previous works in Table VII. We see that the agreement in $P_{33}$ and $D_{13}$ are excellent. For $P_{11}$, there are significant differences between four analysis. As discussed in Ref.[27], it could be mainly due to the differences in the employed reaction models. On the other hand, the difference between the predicted $P_{11}$ amplitudes at $E >$ about 1.6 GeV could be the reason why the third $P_{11}$ pole is not found in Juelich analysis[68].

TABLE VII: The extracted $\pi N$ residues $Re^{i\phi}$ defined by Eq.(114).

**B. Electromagnetic form factors**

We extract the electromagnetic transition form factor of $N^*$ in terms of the residue of resonance poles. This procedure is applied to $\Delta(1232)P_{33}$, $N^*(1520)D_{13}$ and $N^*(1440)P_{11}$ resonances. The resulting form factor is compared with the previous works and the analysis by CLAS. It is noted that helicity amplitudes defined at a real energy introduced in Section IV must be distinguished from the results in this section, which is extracted directly from the resonance pole with complex energy.

For the pion electromagnetic production helicity amplitudes, we replace the initial $\pi N$ state as $\gamma N$ in Section III. Eq. (106) leads to the following expression of electromagnetic form factor,

$$\tilde{\Gamma}_{\gamma^*N}^R = \sum_i \chi_i \tilde{\Gamma}_{\gamma^*N,i}(q^0, M_R),$$  \hspace{1cm} (186)
where
\[ q_0 = \sqrt{\left( \frac{M_R^2 + Q^2 + m_N^2}{2M_R} \right)^2 - m_N^2}. \]  

(187)

The electromagnetic $N-N^*$ transition form factor is defined by matrix element of the electromagnetic currents between nucleon and $N^*$

\[ A_{3/2}(Q^2) = X < N^*, s_z = 3/2 | - \vec{J}(Q^2) \cdot \vec{e}_{+1}| N, s_N = 1/2 >, \]  

(188)

\[ A_{1/2}(Q^2) = X < N^*, s_z = 1/2 | - \vec{J}(Q^2) \cdot \vec{e}_{+1}| N, s_N = -1/2 >, \]  

(189)

\[ S_{1/2}(Q^2) = X < N^*, s_z = 1/2 | J^0(Q^2)| N, s_N = 1/2 >, \]  

(190)

where $\vec{e}_{+1} = -(\hat{x} + i\hat{y})/\sqrt{2}$,

\[ X = \sqrt{\frac{E_N(q)}{m_N}} \frac{1}{\sqrt{2K}}, \]

with $K = (M_R^2 - m_N^2)/(2M_R)$. The above definition was originally introduced for the constituent quark model[66]. If $< N^* |$ is a resonance state, then the above expression at resonance position $M_R$ must be evaluated by using Eq.(106). We thus have

\[ A_{3/2}(Q^2) = X X' \sum_j \chi_j \bar{\Gamma}_{N,j}(Q^2, M_R, \lambda_\gamma = 1, \lambda_N = -1/2), \]  

(191)

\[ X' = \sqrt{\frac{(2j+1)(2\pi)^3(2q_0)}{4\pi}}. \]  

(192)

Here the additional factor $X'$ is due to our normalization of the vertex function $\bar{\Gamma}$. The above helicity amplitudes are in general complex number. $A_{1/2}$ and $S_{1/2}$ have similar expressions.

To extract helicity amplitudes using Eq.(191), we use the multipole amplitudes calculated from using the parameters determined in Ref.[31]. Our results at photon point are listed in Table VIII. We observe that the real parts of our results for $P_{33}$ and $D_{13}$ are in good agreement with several previous results[1, 69–71]. The large differences in $P_{11}$ indicate that more investigations are needed to understand the differences between our resonance extraction method within a coupled-channel model and other methods which are mainly based on the Breit-Wigner parametrization of single channel K-matrix amplitudes.

For $P_{33}$ we can use the standard relation[34] to evaluate the $N-\Delta$ magnetic transition form factor $G_M^*$ in terms of helicity amplitudes. The real parts of our results are the solid
TABLE VIII: The extracted $\gamma N \to N^*$ helicity amplitudes are compared with previous results.

circles in Fig. 43, which are in good agreement with the previous analysis. In the same figure, we also show that the imaginary parts of our results are much weaker. This result and the results of Table VIII suggest that we can only make meaningful comparisons with the results from analysis based on the Breit-Wigner parametrization of single channel K-matrix amplitudes only for the cases that the imaginary parts are small. This turns out to be also the case of the $D_{13}(1521)$ resonance. In Fig. 44, we see that the real parts of our $A_{3/2}$ and $A_{1/2}$ are in good agreement with the results from CLAS collaboration[73]. The large differences in $S_{1/2}$ perhaps are mainly from the fact that the longitudinal parts of the amplitudes can not be well determined with the available data.

![Graph](image-url)

FIG. 43: The magnetic $N-\Delta$ (1232) transition form factor $G^*_M(Q^2)$ defined in Ref.[34]. $G_D = 1./(1 + Q^2/b^2)^2$ with $b^2 = 0.71$ (GeV/c)^2. The solid circles (solid triangles) are the real (imaginary) parts of our results. The other data points are from previous analysis[72].
FIG. 44: The solid circles are the real parts of the extracted $\gamma N \rightarrow N^*(D_{13}(1520))$ form factors. The data are from CLAS collaboration[73]. transition form factors

FIG. 45: The extracted $\gamma N \rightarrow N^*(1356), N^*(1364), N^*(1820)$ transition form factors of $P_{11}$. The solid circles (solid triangles) are their real (imaginary) parts.

For $P_{11}$, almost degenerate two poles are related to the resonance and the imaginary parts of the calculated helicity amplitudes for the three poles are very large. Thus it is not clear how to compare our results with previous results. We thus show both the real parts (solid circles) and imaginary parts (solid triangles) in Fig. 45. It seems that the structure of the pole at 1356 MeV and that of 1364 MeV are similar. In particular their real parts of $A_{1/2}$ change sign at low $Q^2$, similar to what haven been seen in the results from CLAS collaboration[73].

In this subsection, we have extracted the electromagnetic form factor from each pole associated with $N^*(1440)P_{11}$ respectively, but we should treat two poles at the same time because the both of them have influence with the physical sheet. We will investigate the double pole structure and try to develop the method for extracting the resonance parameter of Roper from these two poles in the next subsection.
C. Two pole approximation for $P_{11}$ amplitude

It has been known that two poles are associated with $N^*(1440)P_{11}$ and we have shown the dynamical origin of the two poles is the single bare resonance in this section. The residues of those poles are extracted but it has not been known how to interpret the information of the two poles to understand the nature of the Roper resonance. Here we will present that we can successfully reproduce the $\pi N$ elastic amplitude for $P_{11}$ by applying two-channel Breit-Wigner formula described in Section II to two poles associated with $N^*(1440)$. At present this is a phenomenological attempt for the approximation, but this is an essential step toward extracting the transition form factor of Roper resonance and investigating the method for interpreting resonances which has two-pole structures.

When the resonance energy is close to the threshold energy of opening of a new channel, the convergence radius of Laurent expansion is limited. It is however when we take account of the threshold effects which appear in phase space integral we can extend the pole expansion of the scattering amplitude in a wider energy region. An example is two-channel Breit-Wigner form discussed in Section II,

$$F(E) = \frac{R_1p_1}{E - M + i\gamma_1p_1 + i\gamma_2p_2},$$

where $p_1$ and $p_2$ are the on-shell momentum for the first and second channel. We have seen that two-channel Breit-Wigner formula can be naturally derived from the coupled channel equation.

When the resonance energy is close to the threshold of some channel, we may use an approximate form of the above formula, since only the closest threshold may play a significant role. We use the following formula with the channel momentum $p$ of the newly opening channel,

$$F(E) = -\frac{R + \gamma'p}{E - (M_{res} + \gamma p)} + C + \cdots.$$

This parameterization generates two resonance poles in physical and unphysical sheet of the opening channel. In other words, a single resonance can have a pole in two Riemann sheet. The above parameterization will be extremely useful when both of the two resonance poles are close to the threshold. We write Laurent expansion of the resonance
poles as

\[ F(E) = -\frac{R_i}{E - M_i^{\text{res}}} + c_i, \]  

(195)

with \( i = 1, 2 \) for the poles at physical and unphysical sheets. In this case we can derive resonance parameters \( R, M^{\text{res}}, \gamma, \gamma', C \) from the residue and resonance energy of Eq. (195) from each resonance pole. The parameters are given as

\[
\begin{align*}
\gamma & = \frac{M_1^{\text{res}} - M_2^{\text{res}}}{p_1 - p_2} , \\
M^{\text{res}} & = M_1^{\text{res}} - \gamma p_1 , \\
\gamma' & = \frac{R_1(1 - \gamma dp_1/dE) - R_2(1 - \gamma dp_2/dE)}{p_1 - p_2} , \\
R & = R_1(1 - \gamma dp_1/dE) - p_1 \gamma' , \\
C & = \tilde{C}_1 - dp_1, \\
d & = \frac{\tilde{C}_1 - \tilde{C}_2}{p_1 - p_2} , \\
\tilde{C}_i & = C_i - \frac{dp_i/dE \gamma' + R_i \gamma d^2 p_i/dE^2/2}{1 - \gamma dp_1/dE}.
\end{align*}
\]

(196)-(202)

The above formula can be derived assuming \( C = c_a + c_b p \) and neglect \( c_b \) term since we have not included higher order of the energy dependence.

We applied the above formula for two poles of \( P_{11} \) obtained at Section III A. Fig. 46 shows the full amplitude of \( P_{11} \) by our model shown by red circles and green triangles agrees well with the approximated amplitude by Eq. (193) indicated by red and green lines, which means two-channel Breit-Wigner formula can well describe the amplitude with two-pole structure. If \( \gamma' \) in Eq. (193) is sufficiently small, we can regard \( R \) as the ‘residue’ of the Roper resonance and extract the transition form factor from it, but more discussions may be needed to declare what is the most appropriate method for understanding a resonance with multi-pole structure.

VI. SUMMARY

We have developed an analytic continuation method for extracting resonance parameters such as mass, width, electromagnetic transition form factors from a dynamical reaction model for \( \pi N - \pi N \) and \( \gamma^* N - \pi N \) amplitudes. This is the first application of
FIG. 46: $\pi N$ elastic amplitude of $P_{11}$. The solid circles (solid triangles) are their real (imaginary) parts by the dynamical model. Red (green) line is the real (imaginary) part of approximated amplitudes by Eq. (193).

We have also applied the analytic continuation method to the dynamical coupled channel model of meson production reactions developed in Ref.[28–31]. From the dynamical model, we have extracted pole positions of all partial wave amplitudes and residues of $P_{33}$, $D_{13}$, and $P_{11}$ partial waves. Except the $P_{33}(1600)$, $P_{13}$ and $P_{31}$ cases, pole positions of 3- and 4-star resonances listed by the PDG are consistent with our results. We have shown that two poles associated with $N^*(1440)P_{11}$, which are different in the Riemann sheet of $\pi\Delta$ channel, are originated in the single bare resonance dynamically and another pole at 1820 MeV on $P_{11}$ has the same origin as the two poles. For residues associated with $\pi N$ channel, we agree with most of the previous results[3, 26, 67, 68] for $P_{33}(1232)$, $D_{13}(1521)$ and two $P_{11}$ poles near 1360 MeV. For residues associated with $\gamma^*N$ channel, the corresponding helicity amplitudes for $P_{33}(1232)$ and $D_{13}(1521)$ are dominated by their real parts which are in good agreement with other analysis based on the Breit-Wigner parametrization of K-matrix amplitudes. We have successfully reproduced the $\pi N$ elastic amplitude of $P_{11}$ from two poles corresponding to the Roper resonance by using approximation with two-channel Breit-Wigner formula. With the progress made in this work, we can proceed to extract electromagnetic form factor of $P_{11}(1440)$ from two poles and that of all the other resonances.
Acknowledgments

I am sincerely grateful to Prof. Toru Sato, who is my academic supervisor, for plenty of useful discussions and warm encouragement throughout my research. I also would like to offer my deepest gratitude to Dr. Tung-Shung Harry Lee for many fruitful advices and discussions. I owe a very important debt to Prof. Akihiko Matsuyama, Dr. Bruno Julia-Diaz, Dr. Hiroyuki Kamano and Dr. Satoshi Nakamura for insightful discussions and collaboration. And I am deeply grateful to Prof. Masayuki Asakawa, Prof. Takashi Nakano, Prof. Atsushi Hosaka and Prof. Hiroyuki Noumi for constructive comments and suggestions. I wish to thank all members of the nuclear theory group of Osaka University for useful discussions and much help. Finally, I would like to express my sincere gratitude to my parents for their continuous encouragement and help.
APPENDIX A: NEWTON’S METHOD

We use Newton’s method to obtain a pole position numerically as a zero point of the inverse of $N^*$ propagator on the complex energy plane.

1. Function of single variable

Usual Newton’s method for a function of single variable is

$$f(x_n) + f'(x_n)(x_{n+1} - x_n) = 0, \quad (A1)$$

$$x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)}, \quad (A2)$$

where $f(x_n)$ and $x_n$ are real. Starting from $x_1$ close to a zero point of $f(x)$, we can expect $f(x_n) \simeq 0$ for sufficiently large $n$.

2. Function of multi variables

Supposing two real functions $f_1$ and $f_2$ and two real variables $x$ and $y$, Newton’s method for them is

$$\begin{pmatrix} f_1(x_n, y_n) \\ f_2(x_n, y_n) \end{pmatrix} + \begin{pmatrix} \frac{\partial}{\partial x} f_1(x_n, y_n) & \frac{\partial}{\partial y} f_1(x_n, y_n) \\ \frac{\partial}{\partial x} f_2(x_n, y_n) & \frac{\partial}{\partial y} f_2(x_n, y_n) \end{pmatrix} \begin{pmatrix} x_{n+1} - x_n \\ y_{n+1} - y_n \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}, \quad (A3)$$

or

$$\bar{f}(\bar{x}_n) + J(\bar{x}_n)(\bar{x}_{n+1} - \bar{x}_n) = \bar{0}, \quad (A4)$$

where the matrix $J$ is

$$J(\bar{x}_n) = \begin{pmatrix} \frac{\partial}{\partial x} f_1(x_n, y_n) & \frac{\partial}{\partial y} f_1(x_n, y_n) \\ \frac{\partial}{\partial x} f_2(x_n, y_n) & \frac{\partial}{\partial y} f_2(x_n, y_n) \end{pmatrix}. \quad (A5)$$

$\bar{x}_{n+1}$ is obtained by

$$\bar{x}_{n+1} = \bar{x}_n - J^{-1}(\bar{x}_n)\bar{f}(\bar{x}_n). \quad (A6)$$

The both of $f_1(x_n, y_n)$ and $f_2(x_n, y_n)$ are expected to be zero for large $n$. 
3. Complex function

If we write $f_1$ and $f_2$ by a complex analytic function $\tilde{f}(z)$ as

$$f_1(x_n, y_n) = \text{Re}[\tilde{f}(x_n + iy_n)] = \text{Re}[\tilde{f}(z_n)], \quad (A7)$$

$$f_2(x_n, y_n) = \text{Im}[\tilde{f}(x_n + iy_n)] = \text{Im}[\tilde{f}(z_n)], \quad (A8)$$

we can obtain the zero point of $\tilde{f}(z)$ in the same way as the case of real functions.

APPENDIX B: POLE EXPANSION WITH TWO RESONANCES

In this appendix, we present pole expansion of scattering amplitude with two resonances. Assuming there are two resonances coupling with the meson-baryon system, the propagator of resonant particles becomes a matrix,

$$t_{\text{res}} = \sum_{\alpha,\beta} \Gamma_{f,\alpha} \left( \frac{1}{D} \right)_{\alpha,\beta} \Gamma_{i,\beta}, \quad (B1)$$

where

$$D_{\alpha,\beta} = (W - m_\alpha) \delta_{\alpha,\beta} - \Sigma_{\alpha,\beta}. \quad (B2)$$

The explicit expression of $1/D$ for $2 \times 2$ matrix is

$$\frac{1}{D} = \frac{N}{\Delta}, \quad (B3)$$

$$\Delta = D_{11}D_{22} - D_{12}D_{21}, \quad (B4)$$

$$N = \begin{pmatrix} D_{22} & -D_{12} \\ -D_{21} & D_{11} \end{pmatrix}. \quad (B5)$$

The resonance energy is obtained by

$$\Delta = D_{11}D_{22} - D_{12}D_{21} = 0. \quad (B6)$$

The expansion of the t-matrix around resonance pole is given as

$$T(W) = \frac{R}{W - M} + C_0 + \cdots, \quad (B7)$$
and

\[ R = \frac{\Gamma_f^T(M)N(M)\Gamma_i(M)}{\Delta'(M)}, \]

\[ C_0 = t^{\text{non-res}}(M) + \frac{\Gamma_f^T(M)N(M)\Gamma_i(M) + \Gamma_f^T(M)N(M)\Gamma_i(M)}{\Delta'(M)} - \frac{\Delta''(M)}{2(\Delta'(M))^2} \frac{\Gamma_f^T(M)N(M)\Gamma_i(M) + \Gamma_f^T(N)\Gamma_i(M)}{\Delta'(M)}. \]  

(B8)

Residues for \( \pi N \to \pi N \) scattering \((R_{\pi\pi})\) and pion electroproduction \(\gamma^* N \to \pi N\) \((R_{\gamma\pi})\) are written using \(\pi N\) and \(\gamma N\) form factors \((F_\pi, F_\gamma)\)

\[ R_{\pi\pi} = F_\pi F_\pi, \]

\[ R_{\gamma\pi} = F_\pi F_\gamma. \]  

(B10)

(B11)

In our model \(D_{12} = D_{21}\), therefore \(\Delta(M) = 0\) means

\[ D_{11}(M)D_{22}(M) = D_{12}^2(M) = D_{21}^2(M). \]  

(B12)

Using this one can define form factor as

\[ F_x = a\Gamma_{x,1} + b\Gamma_{x,2}, \]

\[ a = \sqrt{\frac{D_{22}(M)}{\Delta'(M)}}, \]

\[ b = -\frac{D_{12}(M)}{\sqrt{D_{22}(M)\Delta'(M)}}. \]  

(B13)

(B14)

(B15)

APPENDIX C: LAGRANGIANS

In this appendix, we specify a set of Lagrangians for deriving the non-resonant interactions \(v_{MB, M'B'}\) which is the input to the coupled-channel equations Eq.(135). In the convention of Bjorken and Drell[65], the Lagrangian with \(\pi, \eta, N,\) and \(\Delta\) fields are

\[ L_{\pi NN} = -\frac{f_{\pi NN}}{m_\pi} \bar{\psi}_N\gamma_\mu\gamma_5\psi_N \cdot \partial^\mu \phi_{\pi}, \]

\[ L_{\pi N\Delta} = -\frac{f_{\pi N\Delta}}{m_\pi} \bar{\psi}_N \Delta \psi_N \cdot \partial_\mu \phi_{\pi}, \]  

(C1)

(C2)
\[ L_{\pi\Delta} = \frac{f_{\pi\Delta}}{m_{\pi}} x_{\Delta\mu} \gamma_5 T_{\Delta} \partial^\mu \phi_{\pi}, \]  
(C3)

\[ L_{\eta NN} = \frac{f_{\eta NN}}{m_{\eta}} x_{\eta\mu\nu} \gamma_5 x_{\eta} \partial^\mu \phi_{\eta}, \]  
(C4)

\[ L_{\rho NN} = g_{\rho NN} x_{\rho\mu\nu} \gamma_5 x_{\rho} \partial^\mu \phi_{\rho} + [h.c.], \]  
(C5)

\[ L_{\rho\Delta} = \frac{-if_{\rho\Delta}}{m_{\rho}} x_{\rho\Delta\mu} \gamma_5 \gamma_5 T_{\rho} \partial^\mu \phi_{\rho} + [h.c.], \]  
(C6)

\[ L_{\rho\Delta} = g_{\rho\Delta\eta} x_{\rho\Delta\mu} \gamma_5 \gamma_5 T_{\Delta} \partial^\mu \phi_{\rho} + [h.c.], \]  
(C7)

\[ L_{\rho\pi\pi} = g_{\rho\pi\pi} \epsilon_{\mu\nu\rho} \partial^\mu \phi_{\pi} \partial^\nu \phi_{\pi}, \]  
(C8)

\[ L_{\rho NN\rho} = \frac{f_{\rho NN\rho}}{m_{\rho}} g_{\rho NN\rho} x_{\rho\mu\nu} \gamma_5 x_{\rho\nu\phi}_{\rho} \partial^\mu \phi_{\rho}, \]  
(C9)

\[ L_{\rho NN\rho} = \frac{-k_{\rho NN\rho}}{8m_{\rho}} x_{\rho\mu\nu} \gamma_5 x_{\rho\nu\phi}_{\rho} \partial^\mu \phi_{\rho}, \]  
(C10)

\[ L_{\omega NN} = g_{\omega NN} x_{\omega\mu\nu} \gamma_5 x_{\omega} \partial^\mu \phi_{\omega} \partial^\nu \phi_{\omega}, \]  
(C11)

\[ L_{\omega\pi\rho} = \frac{-g_{\omega\pi\rho}}{m_{\omega}} x_{\omega\mu\nu} \gamma_5 x_{\omega} \partial^\mu \phi_{\pi} \partial^\nu \phi_{\rho}, \]  
(C12)

\[ L_{\sigma NN} = g_{\sigma NN} x_{\sigma\mu\nu} \gamma_5 x_{\sigma} \partial^\mu \phi_{\sigma} \partial^\nu \phi_{\sigma}, \]  
(C13)

\[ L_{\sigma\pi\pi} = \frac{-g_{\sigma\pi\pi}}{2m_{\pi}} x_{\sigma\mu\nu} \gamma_5 x_{\sigma} \partial^\mu \phi_{\pi} \partial^\nu \phi_{\pi} \phi_{\sigma}, \]  
(C14)

**APPENDIX D: PARAMETERS FROM THE FITS**

In this appendix, we show the parameters for the dynamical coupled channel model in section IV. They have been obtained by the fitting with the partial wave amplitudes

TABLE XIV: Integral path on complex momentum plane for calculating on-shell $\pi N$ scattering amplitude at the resonance pole.

**APPENDIX E: INTEGRAL PATH**

Tables XIV and XV shows the integral path of each channel, $\pi N, \eta N, \pi\Delta, \sigma N$ and $\rho N$, for calculating $\pi N$ scattering and electromagnetic form factor at the energy of the resonance pole, respectively. The paths are determined to choose the considered Riemann sheet and avoid singularities from the non-resonant potential. For example, in the case of calculating electromagnetic form factor, the path of $\pi\Delta$ momentum at the pole position on $P_{33}$ partial wave is chosen as the straight line of $0 \rightarrow 200 - 100i \rightarrow 800 - 50i \rightarrow \infty - 50i$ MeV.
