A REMARK ON BRAID GROUP ACTIONS ON COHERENT SHEAVES

R. VIRK

(Received January 7, 2013)

Abstract
A general construction of braid group actions on coherent sheaves via M. Saito’s theory of mixed Hodge modules is given.

1. Introduction

Examples of braid group actions on derived categories of coherent sheaves are abundant in the literature. Much of the interest in these stems from the relation with homological mirror symmetry, see [15]. The purpose of this note is to give a construction of braid group actions on coherent sheaves (algebraic) via actions on derived categories of constructible sheaves (topological). The bridge between these worlds is provided by M. Saito’s theory of mixed Hodge modules.

In §3 we review the construction of the main player: $D^b_m(B\backslash G/B)$, the Borel equivariant derived category of mixed Hodge modules on the flag variety $G/B$ associated to a reductive group $G$. The key points are Proposition 3.3 (braid relations) and Theorem 3.8 (invertibility of the objects giving the braid relations). The contents of this section can be found in various forms in the literature, for instance see [16].

Underlying a mixed Hodge module $M$ on a smooth variety $X$ is a filtered $\mathcal{D}$-module. The associated graded is a $C^\ast$-equivariant coherent sheaf $\widehat{\mathcal{G}} M$ on the cotangent bundle $T^*X$. This brings us to the main result, Theorem 4.8, which exploits $\widehat{\mathcal{G}}$ to obtain a monoidal functor from $D^b_m(B\backslash G/B)$ to an appropriate category of coherent sheaves $\mathcal{H}$ on the Steinberg variety. In view of Proposition 3.3 and Theorem 3.8, this realizes our goal. Via standard Fourier–Mukai formalism, $\mathcal{H}$ acts on auxilliary categories of coherent sheaves giving braid group actions on these too.

The idea to exploit $\widehat{\mathcal{G}}$ in this fashion comes from T. Tanisaki’s beautiful paper [17]. This theme was also explored by I. Grojnowski [6]. I. Grojnowski and T. Tanisaki work at the level of Grothendieck groups, we insist on working at the categorical level. Regardless, all the key ideas are contained in [17]. Furthermore, the key technical result (Theorem 4.5) that is used to prove Theorem 4.8 is due to G. Laumon [11].

A variant of Theorem 4.8 has also been obtained by R. Bezrukavnikov and S. Riche [4]. Further, R. Bezrukavnikov and S. Riche were certainly aware of such a result long...
Before this note was born (see [3]). Thus, experts in geometric representation theory have known that such a result must hold for a long time. Certainly V. Ginzburg (see [5]), I. Grojnowski (see [6]), M. Kashiwara (see [7]), D. Kazhdan (see [8]), G. Lusztig (see [8]), R. Rouquier (see [13]), and of course T. Tanisaki (see [17]) must have also known. Undoubtedly this list is woefully incomplete.

2. Conventions

Throughout ‘variety’ = ‘separated reduced scheme of finite type over Spec(C)’. A variety can and will be identified with its set of geometric points. If X is a variety, set \( d_X = \dim \mathbb{C}(X) \). If Y is another variety, set \( d_{X/Y} = d_X - d_Y \).

Write \( \text{MHM}(X) \) for the abelian category of mixed Hodge modules on X, and \( D^b_m(X) \) for its bounded derived category. The constant (mixed Hodge) sheaf is denoted \( \mathcal{O}_X \). Throughout ‘variety’ acts on \( \text{MHM}(X) \) for the abelian subcategory of \( \text{MHM}(X) \) for the structure sheaf of \( X \). If \( X \) is smooth, write \( \omega_X \) for the cotangent sheaf and \( \omega_{X/Y} = \omega_X \otimes_{\mathcal{O}_Y} f^{-1} \omega_Y \).

Let \( f : X \rightarrow Y \) be a morphism of varieties. For coherent sheaves, write \( f^{-1} \) for the ordinary pullback of sheaves, so that the pullback \( f^* : D^b_\mathbb{C}(\mathcal{O}_Y) \rightarrow D^b_\mathbb{C}(\mathcal{O}_X) \) is given by \( f^*M = \mathcal{O}_Y \otimes_{f^{-1} \mathcal{O}_X} f^{-1}M \). If X is smooth, write \( \Omega_X \) for the cotangent sheaf and set \( \omega_X = \bigwedge^{d_X} \Omega_X \). If \( f : X \rightarrow Y \) is a morphism between smooth varieties, set \( \omega_{X/Y} = \omega_X \otimes_{\mathcal{O}_Y} f^{-1} \omega_Y \).

Write \( \mathcal{D}_X \) for the sheaf of differential operators on X. A \( \mathcal{D}_X \)-module will always mean a coherent left \( \mathcal{D}_X \)-module which is quasi-coherent as an \( \mathcal{O}_X \)-module.

We write \( \pi_X : T^*X \rightarrow X \) for the cotangent bundle to a smooth variety X. We identify \( T^*(X \times X) \) with \( T^*X \times T^*X \). However, we do this via the usual isomorphism \( T^*(X \times X) \simeq T^*X \times T^*X \) composed with the antipode map on the right. This is dictated by requiring that the conormal bundle to the diagonal in \( X \times X \) be identified with the diagonal in \( T^*X \times T^*X \).

3. Convolution

Let \( G \) be a connected reductive group. Fix a Borel subgroup \( B \leq G \). Then \( B \) acts on \( G \) via \( b \cdot g = gb^{-1} \). The quotient under this action is the flag variety \( G/B \). Clearly, \( B \) acts on \( G/B \) on the left, and we may form the equivariant derived category \( D^b_m(B \backslash G/B) \).

Let \( \tilde{q} : G \times G/B \rightarrow G/B \) be the projection on \( G \) composed with the quotient map \( G \rightarrow G/B \). Let \( p : G \times G/B \rightarrow G/B \) denote projection on \( G/B \). Further, write
Define a monoidal structure on $\mathbf{G}$ by the action of $\mathbf{G}$ on $G/B$. The convolution bifunctor $-\cdot- : D^b_m(B/G) \times D^b_m(B/G) \to D^b_m(B/G)$ is defined by the formula

\[ M \cdot N = m_i(M \boxtimes N), \]

where $M \boxtimes N$ denotes the descent of $\tilde{q}^* M \otimes p^* N[d_B]$ to $D^b_m(B \times G/B)$. This is an associative operation and endows $D^b_m(B\backslash G/B)$ with a monoidal structure. Convolution adds weights and commutes with Verdier duality, since $m$ is proper.

### 3.1. Another description

The group $G$ acts on $G/B \times G/B$ diagonally. The map $G \times G/B \to G/B \times G/B$, $(g, x) \mapsto (\tilde{q}(g), g \cdot x)$ induces a $G$-equivariant isomorphism

\[ G/B \times G/B \sim G \times G/B. \]

Under this isomorphism $m : G \times G/B \to G/B$ corresponds to projection on the second factor $p_2 : G/B \times G/B \to G/B$. Define $i : G/B \to G/B \times G/B$, $x \mapsto (\tilde{q}(1), x)$. Using equivariant descent (see [12, Lemma 1.4]) we infer

\[ i^*(-d_{G/B}) : D^b_m(G\backslash(G/B \times G/B)) \sim D^b_m(B\backslash G/B) \]

is a t-exact equivalence. If $M \in D^b_m(G\backslash(G/B \times G/B))$ is pure of weight $n$, then $i^*M[-d_{G/B}]$ is pure of weight $-d_{G/B}$.

Let $r = \text{id}_{G/B} \times \Delta \times \text{id}_{G/B}$, where $\Delta : G/B \to G/B \times G/B$ is the diagonal embedding. Define a monoidal structure $-\cdot-$ on $D^b_m(G\backslash(G/B \times G/B))$ by

\[ M \cdot N = p_{13} r^*(M \boxtimes N)[-d_{G/B}], \]

where $p_{13} : G/B \times G/B \times G/B \to G/B \times G/B$ denotes projection on the first and third factor. A diagram chase (omitted) shows that the equivalence (3.1.1) is monoidal. We will constantly go back and forth between these two descriptions.

### 3.2. Braid relations

Fix a maximal torus $T \subseteq B$. Let $W = N_G(T)/T$ be the Weyl group. Write $l : W \to \mathbb{Z}_{\geq 0}$ for the length function. The $B$-orbits in $G/B$ are
indexed by $W$. Further, writing $X_w$ for the orbit corresponding to $w \in W$, we have $X_w \simeq C^{i(w)}$. For each $w \in W$, let $i_w : X_w \hookrightarrow G/B$ be the inclusion map. Set

$$T_w = i_w ! X_w$$

and

$$C_w = IC(X_w, X_w)[-l(w)].$$

Then $T_e$ is the unit for convolution and will be denoted by $1$. Both $T_w [l(w)]$ and $C_w [l(w)]$ are in $MHM(B \backslash G/B)$.

Write $Y_w$ for the image of $G \times X_w$ under the isomorphism (3.1.1). Then the $Y_w$, $w \in W$, are the $G$-orbits in $G/B \times G/B$. Furthermore, $T_w = i^* j_w ! Y_w$ and $C_w = i^* IC(Y_w, Y_w)[-l(w)]$, where $j_w : Y_w \hookrightarrow G/B \times G/B$ is the inclusion map.

**Proposition 3.3.** If $l(w w') = l(w) + l(w')$, then $T_w \cdot T_{w'} = T_{w w'}$.

**Proof.** If $l(w w') = l(w) + l(w')$, then $Y_{w w'} = Y_w \times_{G/B} Y_{w'}$, where the fibre product is over the projection maps $Y_w \rightarrow G/B$ and $Y_{w'} \rightarrow G/B$ on the first and second factor respectively. Now an application of proper base change and the description of convolution on $D^b_m (G \backslash (G/B \times G/B))$ yields the result.

**Lemma 3.4.** $T_w [l(w)] \cdot -$ is left $t$-exact, and $(DT_w)[l(w)] \cdot -$ is right $t$-exact.

**Proof.** It suffices to show $T_w [l(w)] \cdot -$ is left $t$-exact, since Verdier duality commutes with convolution. Consider the diagram

$$
\begin{array}{ccccc}
X_w & \xleftarrow{q_w} & B W B \times G/B & \xrightarrow{q_w} & B W B \times G/B & \xrightarrow{m_w} & G/B \\
& & \downarrow p_w & & \downarrow m_w & & \\
& & G/B & & G/B
\end{array}
$$

where $\tilde{q}_w$ is the the evident quotient map on the first factor followed by projection, $p_w : B W B \times G/B \rightarrow G/B$ is projection on the second factor, $q_w$ is the restriction of $q$, and $m_w$ is the restriction of $m$. Then $T_w \cdot - = m_w ! (X_w \boxtimes -)$, where $X_w \boxtimes -$ is the descent of $\tilde{q}_w^* X_w \otimes p_w^* (-)[d_B]$ to $D^b_m (B \backslash B W B \times G/B)$. Now $X_w [l(w)] \boxtimes -$ is $t$-exact. This implies the result, since $m_w$ is affine.

**Proposition 3.5.** Let $s \in W$ be a simple reflection and $G/P_s$ the corresponding partial flag variety. Let $\pi_s : G/B \rightarrow G/P_s$ be the projection. Then $C_s \cdot M = \pi_s^* \pi_s^* M$, for all $M \in \mathcal{K}^p$.

**Proof.** The closure $\overline{Y}_s$ of $Y_s$ in $G/B \times G/B$ is smooth (it is isomorphic to $\mathbb{P}^1 \times \mathbb{P}^1$). Hence, $IC(Y_s, Y_s) = i_i^! \overline{Y}_s [d_{\overline{Y}_s}]$, where $i : \overline{Y}_s \hookrightarrow G/B \times G/B$ is the inclusion. Further, $\pi_s$
is a Zariski locally trivial $\mathbb{P}^1$-fibration. Using proper base change we deduce

$$(j_{s!}Y_1^*[d_{Y_1} - 1]) \cdot N = (\text{id}_{G/B} \times \pi_s)^*(\text{id}_{G/B} \times \pi_s)_*N$$

for all $N \in D^b_m(G \setminus (G/B \times G/B))$. Further, if $\tilde{M} \in D^b_m(G \setminus (G/B \times G/B))$ is such that $i^*\tilde{M}[-d_{G/B}] = M$, then

$$i^*(\text{id}_{G/B} \times \pi_s)^*(\text{id}_{G/B} \times \pi_s)_*\tilde{M}[-d_{G/B}] = \pi_s^*\pi_s_*M.$$  

\[\square\]

**Corollary 3.6.** Let $s \in W$ be a simple reflection. Then $C_s \cdot C_s = C_s \oplus C_s[-2](-1)$.

Let

$$i: D^b_m(B \setminus G/B) \xrightarrow{\sim} D^b_m(B \setminus G/B)$$

denote the auto-equivalence induced by the automorphism of $G/B \times G/B$ that switches the factors. Then $i(M \cdot N) = iN \cdot iM$, for all $M, N \in D^b_m(B \setminus G/B)$. Further, if $s \in W$ is a simple reflection, then $iT_s = T_s$. Consequently, $iT_w = T_{w^{-1}}$ and $iC_w = C_{w^{-1}}$ for all $w \in W$.

**Proposition 3.7.** Let $s \in W$ be a simple reflection. Then

(i) $C_s \cdot T_s = C_s[-2](-1) = T_s \cdot C_s$;

(ii) $T_s \cdot DT_s = 1 = DT_s \cdot T_s$.

Proof. Proposition 3.5 gives the first equality in (i), and applying the involution $i$ gives the second equality. Convolve the distinguished triangle $DT_s \to 1[1] \to C_s[3](1)$ with $T_s$, and use (i) along with Lemma 3.4 to get a short exact sequence

$$0 \to T_s \cdot DT_s \to T_s[1] \to C_s[1] \to 0$$

in $\text{MHM}(B \setminus G/B)$. This implies $T_s \cdot DT_s = 1$. That $DT_s \cdot T_s = 1$ follows from Verdier duality.  

Combining Proposition 3.3 with Proposition 3.7 (ii) yields:

**Theorem 3.8.** Each $T_w, w \in W$, is invertible under convolution.

4. Action on coherent sheaves

Let $X$ be a smooth variety and $\pi_X: T^*X \to X$ its cotangent bundle.
4.1. Filtered $\mathcal{D}$-modules. Let $F_i(\mathcal{D}_X)$ denote the sub-sheaf of $\mathcal{D}_X$ consisting of differential operators of degree at most $i$. This defines a filtration of $\mathcal{D}_X$. Write $gr \mathcal{D}_X$ for the associated graded sheaf of rings. Then we have a canonical isomorphism

$$gr \mathcal{D}_X \simeq \pi_{X*}\mathcal{O}_{T^*X}. $$

Identify $gr \mathcal{D}_X$ with $\pi_{X*}\mathcal{O}_{T^*X}$ via this isomorphism. A filtered $\mathcal{D}_X$-module is a pair $(M, F)$, where $M$ is a $\mathcal{D}_X$-module and $F$ is an exhaustive filtration of $M$ by sub-sheaves such that $F_i(\mathcal{D}_X)F_jM \subseteq F_{i+j}M$. The filtration $F$ is a good filtration if $gr(M)$ is coherent as a $gr \mathcal{D}_X$-module. The support of $\mathcal{O}_{T^*X} \otimes_{\pi^n} gr \mathcal{D}_X gr(M)$ is the characteristic variety of $M$.

A mixed Hodge module $M \in MHM(X)$ is a tuple $(M, F, rat(M), W)$, where $M$ is a regular holonomic $\mathcal{D}_X$-module, $F$ is a good filtration on $M$ (the Hodge filtration), $rat(M)$ is a perverse sheaf on $X$ with $\mathbb{Q}$-coefficients (the rational structure) such that $\mathbb{D}\mathcal{R}(M) = C \otimes_{\mathbb{Q}} rat(M)$, where $\mathbb{D}\mathcal{R}$ is the de Rham functor, and $W$ is the weight filtration on $(M, F, rat(M))$. This data is required to satisfy several compatibilities which we only recall as needed. Morphisms in $MHM(X)$ respect the filtrations $F$ and $W$ strictly. Given $(M, F, rat(M), W) \in MHM(X),

$$M(n) = (M, F_{*n}, Q(n) \otimes_{\mathbb{Q}} rat(M), W_{*+2n}), $$

where $Q(n) = (2\pi \sqrt{-1})^n Q$.

The weight filtration $W$ and rational structure $rat(M)$ are not particularly relevant for us in this section. Consequently, we omit them from our notation from here on and focus on the filtered $\mathcal{D}$-module structure underlying a mixed Hodge module.

4.2. The functor $\overline{gr}$. Let $(M, F) \in MHM(X)$. Taking the associated graded with respect to $F$ gives a coherent $gr(\mathcal{D}_X)$-module $gr(M)$. Hence, we obtain an exact functor from $MHM(X)$ to graded coherent $gr(\mathcal{D}_X)$-modules. We have $C^*$ acting on $T^*X$ via dilation of the fibres of $\pi_X$. As $\pi_X$ is affine, $\pi_{X*}$ gives an equivalence between $C^*$-equivariant quasi-coherent $\mathcal{O}_{T^*X}$-modules and graded quasi-coherent $\pi_{X*}\mathcal{O}_{T^*X}$-modules. Thus, we obtain an exact functor

$$\overline{gr}: MHM(X) \to Coh^{C^*}(\mathcal{O}_{T^*X}), \quad M \mapsto \mathcal{O}_{T^*X} \otimes_{\pi^n} gr \mathcal{D}_X \pi^{-1}X gr(M), $$

with $C^*$ action on $\overline{gr}(M)$ defined by

$$z \cdot (f(x, \xi) \otimes m_i) = f(x, z^{-1}\xi) \otimes z^{-1}m_i,$$

where $z \in C^*$, $f(x, \xi) \in \mathcal{O}_{T^*X}$, and $m_i$ is in the $i$-th component of $gr(M)$.

4.3. Tate twist and $\overline{gr}$. For $n \in \mathbb{Z}$ let $q^n \in Coh^{C^*}(pt)$ be the one dimensional $C^*$-module with the action of $z \in C^*$ given by multiplication by $z^n$. Let $a: T^*X \to pt$
be the obvious map. For \( M \in D^C(O_{T^*X}) \), set \( M(n) = a^*q^n \otimes_{O_{T^*X}} M \). Evidently, if \( N \in D^b_m(X) \), then
\[
\tilde{\text{gr}}(N(n)) = \tilde{\text{gr}}(N(n)).
\]

4.4. Correspondences. Let \( f : X \rightarrow Y \) be a morphism of smooth varieties. Associated to \( f \) we have the diagram
\[
T^*X \xleftarrow{f_d} T^*Y \xrightarrow{f_s} T^*Y,
\]
where \( f_n \) is the base change of \( f \) along \( T^*Y \rightarrow Y \), and \( f_d \) is the map dual to the derivative. Let \( T^*_X \subseteq T^*X \) denote the zero section. Set
\[
T^*_X = f_d^{-1}(T^*_X).
\]
If \( f \) is the inclusion of a closed subvariety, then \( T^*_X \) is the conormal bundle to \( X \) in \( T^*Y \). Let \( \Lambda \subseteq T^*Y \) be a conic (i.e. \( \mathbb{C}^* \)-stable) subvariety. Then \( f \) is non-characteristic for \( \Lambda \) if
\[
f_{\pi}^{-1}(\Lambda) \cap T^*_X \subseteq T^*_Y \times_Y X.
\]
This is equivalent to \( f_d|_{f_\pi^{-1}(\Lambda)} \) being finite. We say \( f \) is non-characteristic for \( M \in \text{MHM}(X) \) if \( f \) is non-characteristic for the characteristic variety of \( M \).

Let \( X \leftarrow Z \xrightarrow{g} Y \) be a diagram of smooth varieties such that the canonical map \( Z \rightarrow X \times Y \) is a closed immersion. We call such a diagram a correspondence between \( X \) and \( Y \). Associated to a correspondence we have a functor
\[
\Phi_{X|Y} : D^b_m(X) \rightarrow D^b_m(Y), \quad M \mapsto g_* f^*M.
\]
We also have a commutative diagram
\[
\begin{array}{c}
\text{T}^*X \xleftarrow{f_n} \text{T}^*X \times_X Z \xrightarrow{f_d} \text{T}^*Z \xrightarrow{g_d} \text{T}^*Z \xrightarrow{g_*} \text{T}^*Y
\end{array}
\]
with middle square cartesian. So we obtain a correspondence
\[
T^*X \xleftarrow{q_X} T^*_Z(X \times Y) \xrightarrow{q_Y} T^*Y.
\]
For \( M \in D^C(O_{T^*X}) \) set
\[
\tilde{\Phi}_{X|Y}(M) = q_Y(q_X^* M \otimes_{\mathcal{O}_{T^*_Z(X \times Y)}} \rho^* \omega_{Z/Y})[d_{Z/X}](d_{Z/Y}).
\]
where $\rho: T^*_Z(X \times Y) \to Z$ is the evident map.

**Theorem 4.5** ([11, Théorème 3.1.1]). Let $X \xleftarrow{f} Z \xrightarrow{g} Y$ be a correspondence with $g$ projective. If $f$ is non-characteristic for $M \in D^b_m(X)$, then

$$\gr \circ \Phi_{X|Y}(M) = \tilde{\Phi}_{X|Y} \circ \gr(M).$$

**Remark 4.6.** Let $f: X \to Y$ be a morphism between smooth varieties, and write $\Gamma_f \subseteq X \times Y$ for the graph of $f$. Let $p_X: \Gamma_f \to X$ and $p_Y: \Gamma_f \to Y$ be the projection maps. Then we have the correspondence

$$X \xleftarrow{p_X} \Gamma_f \xrightarrow{p_Y} Y,$$

and $\Phi_{X|Y} = f_*$. If $f$ is projective, then Theorem 4.5 implies

$$\gr f_* = f_{\pi*}f_d^! \gr[d_{X|Y}](d_{X|Y}).$$

Similarly, for the correspondence

$$Y \xleftarrow{p_Y} \Gamma_f \xrightarrow{p_X} X,$$

one has $\Phi_{Y|X} = f^*$. If $f$ is smooth, then Theorem 4.5 implies

$$\gr f^* = f_{d*}f_{\pi*} \gr[d_{X|Y}].$$

Although we have obtained the above formulae as consequences of Theorem 4.5, the proof of Theorem 4.5 proceeds by first obtaining these formulae. Further, in [10] and [11] the formulae do not keep track of the $\mathrm{C}^\times$-equivariant structure. Regardless, the (equivariant) formula for non-characteristic pullback is immediate from the definitions. The (equivariant) formula for proper pushforward requires a bit more work which is done in [17, Lemma 2.3]. With these in hand the proof of Theorem 4.5 proceeds exactly as that of [11, Théorème 3.1.1]. We also note that [10] and [11] are written purely in the context of filtered $\mathcal{D}$-modules. In this generality [11, Théorème 3.1.1] does not quite hold - a crucial ‘strictness’ assumption that is required for the formula for $\gr f_*$ is missing. However, this is not a problem for us: if the filtered $\mathcal{D}$-module structure is one underlying a mixed Hodge module, then this strictness assumption holds ([14, Théorème 1]).

**4.7. The Steinberg variety.** Let $\pi: \mathcal{N} \to G/B$ denote the cotangent bundle of $G/B$. Then $G \times \mathbb{C}^\times$ acts on $\mathcal{N}$ (the map $\pi$ is $G$-equivariant and $\mathbb{C}^\times$ acts via dilations of the fibres of $\pi$). Under our conventions, $\mathcal{N} \times \mathcal{N}$ is the cotangent bundle of $G/B \times G/B$. Further, $G \times \mathbb{C}^\times$ acts on $\mathcal{N} \times \mathcal{N}$ via the diagonal action. The *Steinberg variety*
Z \subseteq \mathcal{N} \times \mathcal{N} \text{ is defined by }

Z = \bigcup_{w \in W} T^w_{\mathcal{N}}(G/B \times G/B).

It is a closed $G \times \mathbb{C}^*$ stable subvariety of $\mathcal{N} \times \mathcal{N}$. The projection $Z \to \mathcal{N}$ to either of the two factors is projective.

Denote by $\tilde{p}_{13} : \mathcal{N} \times \mathcal{N} \times \mathcal{N} \to \mathcal{N} \times \mathcal{N}$ the projection on the first and third factor, and let $p_2 : \mathcal{N} \times \mathcal{N} \times \mathcal{N} \to \mathcal{N}$ be projection on the second factor. Define $\tilde{r} : \mathcal{N} \times \mathcal{N} \times \mathcal{N} \to \mathcal{N} \times \mathcal{N} \times \mathcal{N} \times \mathcal{N}$ by

$$\tilde{r} = \text{id}_{\mathcal{N}} \times \Delta \times \text{id}_{\mathcal{N}},$$

where $\Delta : \mathcal{N} \to \mathcal{N} \times \mathcal{N}$ is the diagonal embedding. Let $\mathcal{H} \subseteq \mathcal{D}^c_{\mathcal{O}_{\mathcal{N} \times \mathcal{N}}}$ be the full subcategory consisting of complexes whose cohomology sheaves are supported on $Z$. Define a bifunctor $- \cdot -$ : $\mathcal{H} \times \mathcal{H} \to \mathcal{H}$ by the formula

$$M \cdot N = \tilde{p}_{13} \tilde{r}^*(M \boxtimes N).$$

This endows $\mathcal{H}$ with a monoidal structure. The unit is $\Delta_* \mathcal{O}_\Delta$.

Define $\gamma : \mathcal{D}^c(G \setminus (G/B \times G/B)) \to \mathcal{H}$ by

$$\gamma(M) = \mathcal{F} \text{For}(M) \otimes_{\mathcal{O}_{\mathcal{N} \times \mathcal{N}}} \Delta_* \pi^* \omega_{G/B}^1(-d_{G/B}).$$

**Theorem 4.8.** $\gamma$ is monoidal.

Proof. That $\gamma$ preserves the unit object can be seen directly. Now apply Theorem 4.5 to the correspondence

$$G/B \times G/B \times G/B \times G/B \xrightarrow{r} G/B \times G/B \times G/B \xrightarrow{p_{13}} G/B \times G/B.$$  

The $G$-equivariance of $M$ and $N$ implies that the characteristic variety of $M \boxtimes N$ is contained in $Z$. Further, $r$ is non-characteristic for $M \boxtimes N$. Consequently,

$$\gamma(M \cdot N) = \gamma(M) \cdot \gamma(N).$$

To complete the proof we need to argue that the associativity constraints on both sides are compatible. The associativity constraint on either side is defined via the usual adjunction maps and base change (iso)morphisms. These are compatible with each other by [11, §2.6].
