THE LIFTED FUTAKI INVARIANTS AND
THE SPIN\textsuperscript{c}–DIRAC OPERATORS

Dedicated to the memory of Professor Masahisa Adachi

KENJI TSUBOI

(Received August 17, 1992)

1. Introduction

The Futaki invariant $f$ which is a Lie algebra homomorphism (cf. [6]) is naturally lifted to a Lie group homomorphism $F$ by virtue of the result in [10]. In [11], we obtained a formula to calculate $2^{n+1} F$ and showed that $F$ can be non-trivial even when no nonzero holomorphic vector field exists. Our purpose in this paper is to refine the formula in [11] so that we can calculate $F$ itself (Theorem 2.10). When $M$ is a Kähler surface with $c_1(M)>0$, the group of holomorphic automorphisms of $M$ (for generic complex structures) are classified (cf. [14]) and, using Theorem 2.10 and the results in [18], [19], we can show that $F$ vanishes if and only if $M$ admits a Kähler-Einstein metric (Theorem 3.6). Moreover we show that $F$ vanishes for some Kähler manifolds which are shown recently to admit a Kähler-Einstein metric (cf. [16]). Futaki conjectured that $F$ as well as $f$ is an obstruction to the existence of Kähler-Einstein metrics on a compact Kähler manifold with $c_1(M)>0$. We might take the results obtained in this paper to encourage the Futaki’s conjecture.

Now let $M$ be a compact $n$-dimensional complex manifold. A Kähler metric $h$ is called a Kähler-Einstein (which is abbreviated to K-E hereafter) metric if there exists a real constant $k$ such that

$$\rho(h) = k\omega(h)$$

where $\rho(h)$ is the Ricci form of $h$ and $\omega(h)$ is the fundamental 2-form of $h$. Note that the first Chern class $c_1(M)$ has a definite sign (namely, $c_1(M)>0$, $c_1(M)=0$ or $c_1(M)<0$ according to $k>0$, $k=0$ or $k<0$) if $M$ admits a K-E metric because $c_1(M)$ is represented by $\rho(h)$. The converse is true when $c_1(M)=0$ or $c_1(M)<0$.

**Theorem 1.1.** ([3], [21]) Let $M$ be a Kähler manifold with $c_1(M)=0$ or $<0$. Then $M$ admits a K-E metric.
So the problem is whether $M$ admits a K-E metric if $c_1(M) > 0$.

Now let $A(M)$ be the Lie group of all holomorphic automorphisms of $M$ and $H(M)$ its Lie algebra consisting of all holomorphic vector fields on $M$. When $c_1(M) > 0$ and $H(M) \neq \{0\}$, there exists an obstruction to the existence of K-E metrics called the Futaki invariant (cf. see [6]). The Futaki invariant $f : H(M) \to \mathbb{C}$ can be expressed as follows:

\[(1.2) f(X) = \frac{(n+1)i}{2\pi} \int_M \text{div}_h(X) \omega(h)^n \]

for any $X \in H(M)$ where $h$ is any Kähler metric on $M$ and $\text{div}_h$ is the divergence with respect to $h$. It is shown [6], [10] that $f(X)$ is determined only by the complex structure of $M$ and is independent of the choice of $h$ and that $f$ is a Lie algebra homomorphism. ($\mathbb{C}$ is regarded as a trivial Lie algebra.) If $h$ is a K-E metric, the right term of (1.2) is equal to

\[f(X) = \frac{(n+1)i}{2\pi} \int_M \text{div}_h(X) \omega(h)^n\]

which equals to 0 by the divergence formula. Since $f(X)$ is independent of the choice of $h$, the following result can be deduced.

**Theorem 1.3.** [6] If $M$ admits a K-E metric, then $f(X) = 0$ for any $X \in H(M)$.

When $H(M) = \{0\}$, there is no known obstruction to the existence of K-E metrics, and it is not known whether there exists an example of $M$ such that $c_1(M) > 0$, $H(M) = \{0\}$ but $M$ does not admit any K-E metric.

On the other hand, by virtue of the result in [10], $f$ can naturally be lifted to a group homomorphism $F : A(M) \to \mathbb{C}/\mathbb{Z}$ as follows.

**Definition 1.4.** Fix any $g \in A(M)$. Let $M_g$ denote the mapping torus $M_g = M \times [0,1]/\sim$ where $(p,0) \sim (g(p),1)$. Let $\mathcal{F}_g$ denote the holomorphic foliation defined by the $[0,1]$-directed vector field. Then, by definition,

\[(1.5) F(g) = Sc_1^{n+1}(\nu(\mathcal{F}_g))[M_g] \in \mathbb{C}/\mathbb{Z} \]

where $[M_g]$ is the fundamental cycle of $M_g$ and

\[Sc_1^{n+1}(\nu(\mathcal{F}_g)) \in H^{2n+1}(M_g; \mathbb{C}/\mathbb{Z})\]

is the Simons character of the first Chern class $c_1$ to the power $n + 1$ for the normal bundle $\nu(\mathcal{F}_g)$ with respect to any Bott connection. (For details, see [10], [17].)
Then, it is shown [7] that $F: A(M) \rightarrow C/Z$ is a Lie group homomorphism where $C/Z$ is regarded as an additive group, and the following holds.

**Theorem 1.6.** [10] We have $F(\exp X) = f(X) \mod Z$ for any $X \in H(M)$. In particular, we have $F_* = f$.

Though it immediately follows from Theorem 1.3 and Theorem 1.6 that $F|_{A_0(M)}$ (where $A_0(M)$ denotes the identity component of $A(M)$) is an obstruction to the existence of K-E metrics on $M$, it is not known whether $F$ itself is an obstruction to the existence of K-E metrics on $M$ or not. If the Futaki's conjecture turns out to be true, $F$ may become the unique obstruction which is valid even when $H(M) = \{0\}$.

**Remark 1.7.** In [9], $f$ is lifted to a group homomorphism $\det \circ \phi: A(M) \rightarrow C^*$ ($\simeq C/Z$). A multiple of $f$ gives rise to a power of the lifting. Theorem 1.6 implies that $f$ is normalized so as to satisfy the integrability condition that $f(X)$ is an integer for any $X \in H(M)$ such that $\exp X = 1$.

2. A calculation formula for $F$

Let $M$ be a compact $n$-dimensional complex manifold and $M_g$ the mapping torus for $g \in A(M)$ defined as in Definition 1.4. In [11], we showed that $2n^2 + 1 F$ is equal to the eta invariant of the signature operator on $M_g$. In this section, we shall show a similar formula by using the spin\(^c\)-Dirac operators.

Now fix an element $g \in A(M)$ which we assume has a finite order $p \geq 2$. (Note that $A(M)$ itself is a finite group if $c_1(M) > 0$ and $H(M) = \{0\}$.) We may assume that $g$ preserves the Hermitian metric $h$ on $M$. Then the Hermitian connection $\nabla^M$ of the holomorphic tangent bundle $TM$, which is uniquely determined under the conditions that the connection form of $\nabla^M$ is of type $(1,0)$ and that $\nabla^M$ preserves $h$, is necessarily $g$-invariant.

Let $X = M \times D^2, \ Y = \partial X = M \times S^1$ be spin\(^c\)-manifolds with the spin\(^c\)-structures defined by the $U(n)$-structure of $M$ and the trivial spin\(^c\)-structures of $D^2, S^1$, respectively. Then the cyclic group $K = \mathbb{Z}_p = \langle g \rangle$ acts on $(X, Y)$ as follows:

$$g(m, re^{i \theta}) = (g(m), re^{i(\theta + 2\pi/p)})$$

for $(m, re^{i \theta}) \in X = M \times D^2; 0 \leq r \leq 1, 0 \leq \theta \leq 2\pi$. Note that $Y/K = M_g$, $(TM \times S^1)/K = \nu(F_g)$ and that $\nabla^M$ naturally defines a Bott connection $\nabla^F$ of $\nu(F_g)$. On the other hand, we give a rotationally symmetric Hermitian metric on the complex manifold $D^2$ such that it is a product metric of $S^1 \times [0, \delta)$ near the boundary $\partial D^2 = S^1$. Then the complex structures and the Hermitian metrics on $M, D^2$ define a $K$-invariant complex structure and a $K$-invariant Hermitian metric on $X$. Let $\nabla^X$ be the $K$-invariant Hermitian connection of $TX$. Then $\nabla^X|_Y$ descends to
a Hermitian connection $\nabla^{X/K}$ of $T(X/K)|_{M_g}$ and it can be shown

$$T(X/K)|_{M_g} = (TX|_Y)/K = \nu(F_g) \oplus \varepsilon$$

where $\varepsilon$ denotes the trivial complex line bundle of all $F_g$-directed vectors and $\nabla^{X/K}$ splits as

$$\nabla^{X/K} = \nabla^F \oplus \nabla^0$$

where $\nabla^0$ denotes the globally flat connection of $\varepsilon$.

Now, since $M_g$ is a stably almost complex manifold, it follows from the result of Morita[15] that there exists a compact $(2n+2)$-dimensional almost complex manifold $W$ such that $\partial W = M_g$ and $W = X/K$ near $M_g$ as an almost complex manifold with a Hermitian metric. Then we have the following lemma by the same arguments as in the proof of Theorem 3.7 in [11].

**Lemma 2.1.** We have $F(g) = \int_W c_1(TW)^{q+1}$ where $c_1(TW)$ is the first Chern form of $TW$ with respect to a unitary connection $\nabla^W$ of $TW$ (namely, $\nabla^W$ preserves the metric and the almost complex structure on $TW$) which coincides with $\nabla^{X/K}$ near $M_g$.

Now, let $\xi$ be the virtual complex vector bundle over $M$ defined by

$$\xi = \otimes^{n+1}(K_M^{-1} \ominus \varepsilon)$$

where $K_M^{-1}$ is the anticanonical bundle of $M$ and $\varepsilon$ is the trivial complex line bundle over $M$. Set $\xi_x = q_x^*\xi$ and $\xi_y = q_y^*\xi$ where $q_x: X = M \times D^2 \to M$ and $q_y: Y = M \times S^1 \to M$ are the canonical projections. $\xi_x$ and $\xi_y$ are virtual vector bundles with unitary connections with respect to the metrics and the connections naturally defined by the Hermitian metric and the Hermitian connection of $TM$. Using the spin$^c$-structures, the metrics and the connections of $TX$ and $TY$, we can define the spin$^c$-Dirac operators (or Dolbeault operators)

$$(2.2) \quad \begin{align*}
D_X &: \Gamma(E_X^+ \otimes \xi_x) \to \Gamma(E_X^- \otimes \xi_x) \\
D_Y &: \Gamma(E_Y \otimes \xi_y) \to \Gamma(E_Y \otimes \xi_y)
\end{align*}$$

where $E_X^\pm$ denote the half spinor bundles over $X$ and $E_Y = E_X^+|_Y = E_X^-|_Y$ is the spinor bundle over $Y$. (For details of spin$^c$-Dirac operators and Dolbeault operators on almost complex manifolds, see [12],[13].) Since the metric and the connection of $TX$ is $K$-invariant and is product near $\partial X = Y$, $D_X$ and $D_Y$ are $K$-invariant and $D_X$ can be expressed as

$$(2.3) \quad D_X = \sigma \left( \frac{\partial}{\partial u} + D_Y \right)$$

on the collar $Y \times [0,\delta) \subset X$ where $u$ is the coordinate of $[0,\delta)$ and $\sigma$ is a bundle.
**Theorem 2.4.** [1] We have

$$\text{Index}(D_x) = \int_X Ch(\xi_x)Td(X) - \frac{1}{2}(\eta_Y + h_Y)$$

where \(\text{Index}(D_x)\) is the index of \(D_x\) with a certain global boundary condition, \(Ch(\xi_x)\) is the Chern character form of \(\xi_x\) with the unitary connection, \(Td(X)\) is the Todd form of \((TX, V^X)\), \(\eta_Y\) is the eta invariant of \(D_Y\) and \(h_Y = \dim(\text{Ker} \ D_Y)\).

Now, let \(\xi_g = \xi_Y/K\) be a virtual vector bundle over \(M_g\) with a unitary connection. Then, since \(D_Y\) is \(K\)-invariant, \(D_Y\) naturally defines a differential operator \(D_g\), which is the \(\xi_g\)-valued spin\(^c\)-Dirac operator on \(M_g = Y/K\). Our first result is the following.

**Theorem 2.5.** We have

$$F(g) = -\frac{1}{2} \eta_g \pmod{Z}$$

where \(\eta_g\) is the eta invariant of \(D_g\).

**Proof.** Set

$$\xi_w = \otimes^{n+1}(\wedge^{n+1} TW - \varepsilon)$$

where \(\varepsilon\) denotes the trivial complex line bundle over \(W\). Note that \(\wedge^{n+1} TW\) is also a complex line bundle over \(W\). The unitary connection \(V^W\) of \(TW\) naturally defines a unitary connection of \(\xi_w\). Then the spin\(^c\)-Dirac operator

$$D_w : \Gamma(E_w^+ \otimes \xi_w) \rightarrow \Gamma(E_w^- \otimes \xi_w)$$

is defined similarly as in (2.2). It can be seen that \(\xi_w|_{M_g} = \xi_g\) and, similarly as in (2.3), \(D_w\) can be expressed as

$$D_w = \sigma \left( \frac{\partial}{\partial u} + D_g \right)$$

on the collar \(M_g \times [0, \delta) \subset W\). Hence it follows from the Atiyah-Patodi-Singer's theorem (cf. Theorem 2.4) that

$$\int_W Ch(\xi_w)Td(W) = \frac{1}{2}(\eta_g + h_g) \pmod{Z}$$

where \(Ch(\xi_w)\) is the Chern character form of \(\xi_w\), \(Td(W)\) is the Todd form of \(TW\).
and $h_g = \dim(\ker D_g)$. Since

$$Ch(\xi_W) = (Ch(\Lambda^{n+1}TW) - 1)^{n+1} = (c_1(TW))^{n+1}$$

and the leading term of $Td(W)$ is equal to 1, it follows from Lemma 2.1 that

$$F(g) = \frac{1}{2} (\eta_g + h_g).$$

Therefore the theorem follows from Lemma 2.6 below.

**Lemma 2.6.** We have $\frac{1}{2} h_g = 0 \mod Z$.

Proof. Since the spin$^c(2n+1)$-structure of $M_g$ comes from the natural $U(n)$-structure of $M_g$, the spinor bundle $E_g = E_g/K$ on $M_g$ splits into $E_g = E^+_g \oplus E^-_g$ and $D_g$ splits into $D_g = D^+_g \oplus D^-_g$ where

$$D^+_g : \Gamma(E^+_g \otimes \xi_g) \rightarrow \Gamma(E^-_g \otimes \xi_g)$$

$$D^-_g = (D^+_g)^* : \Gamma(E^-_g \otimes \xi_g) \rightarrow \Gamma(E^+_g \otimes \xi_g)$$

Hence we have

$$h_g = \dim(\ker D_g) = \dim(\ker D^+_g) + \dim(\ker D^-_g).$$

On the other hand, since the dimension of $M_g$ is odd, it follows that

$$\text{Index}(D^+_g) = \dim(\ker D^+_g) - \dim(\ker(D^+_g)^*) = 0.$$

Therefore we have

$$\dim(\ker D^-_g) = \dim(\ker(D^+_g)^*) = \dim(\ker D^+_g)$$

and hence we have

$$\frac{1}{2} h_g = \dim(\ker D^+_g) \in Z.$$

This completes the proof.

Now, let $\Omega(k) \subset X$ be the fixed point set of $g^k \in K$ $(1 \leq k \leq p - 1)$ which is the disjoint union of compact connected complex submanifolds $N$. Note that the fixed point set $\Omega(k) \subset X$ of the $g^k$-action on $X$ coincides with the fixed point set $\Omega(k) \subset M = M \times \{0\} \subset X$ of the $g^k$-action on $M$. Let $\nu(N, X), \nu(N, M)$ be the normal bundle of $N$ in $X, M$, respectively. Then $\nu(N, M)$ is decomposed into the direct sum of subbundles

$$\nu(N, M) = \bigoplus_j \nu(N, \theta_j)$$

(2.7)
where $g^k$ acts on $v(N, \theta_j)$ via multiplication by $e^{i\theta_j}$.

**Definition 2.8.** We define the characteristic class $\gamma(v(N, \theta_j))$ by

$$\gamma(v(N, \theta_j)) = \prod_{k=1}^{r} \frac{1}{1 - e^{-x_k - i\theta_j}} \in H^{*+}(N; \mathbb{C}) \quad (r = \text{rank}(v(N, \theta_j)))$$

where $\Pi_k(1 + x_k)$ equals to the total Chern class of $v(N, \theta_j)$.

Since $v(N, X)$ is decomposed into the direct sum

$$v(N, X) = v(N, M) \oplus \varepsilon$$

and $g^k$ acts on the trivial complex line bundle $\varepsilon$ over $N$ via multiplication by $e^{2\pi ik/p}$, the following lemma can be deduced from Theorem 1.2 in [5]. (See also Lemma 3.5.4 in [12] and (4.6) in [2].)

**Lemma 2.9.** Fix any $g^k$ $(1 \leq k \leq p - 1)$. Suppose that $g^k$ acts on $K_M^{-1}|_N$ via multiplication by $e^{i\varphi(k)}$. Then we have

$$\text{Index}(D_X, g^k) = \sum_{N \in D(k)} \frac{1}{1 - e^{-2\pi ik/p}} e^{i\varphi(k)} \text{Ch}(K_M^{-1}|_N) - 1)^{r+1} \text{Td}(N)[N] \prod_j \gamma(v(N, \theta_j))[N]$$

$$- \frac{1}{2} (\eta_T(g^k) + \text{Tr}(g^k|_{\ker D_T}))$$

where $\text{Index}(D_X, g^k)$ is the index of $D_X$ with the global boundary condition in Theorem 2.4 evaluated at $g^k$, namely,

$$\text{Index}(D_X, g^k) = \text{Tr}(g^k|_{\ker D_X}) - \text{Tr}(g^k|_{\text{Coker } D_X})$$

(Note that $\text{Index}(D_X, 1) = \text{Index}(D_X)$, $\text{Ch}(K_M^{-1}|_N)$ is the Chern character of $K_M^{-1}|_N$, $\text{Td}(N)$ is the Todd class of $TN$, $[N]$ is the fundamental cycle of $N$ and $\eta_T(g^k)$ is the eta invariant of $D_T$ evaluated at $g^k$ (cf. [5]). (Note that $\eta_T(1)$ is equal to $\eta_T$ in Theorem 2.4.)

Using Lemma 2.9 and the fact that

$$\text{Ch}(K_M^{-1}|_N) = e^{c_1(K_M^{-1}|_N)} = e^{c_1(TM)|_N} = e^{c_1(N) + c_1(v(M, M))}$$

where $c_1(N)$ is the first Chern class of $TN$, we can obtain the following theorem.

**Theorem 2.10.** In the notation of the above lemma, we have

$$F(g) = \sum_{k=1}^{p-1} \sum_{N \in D(k)} \frac{1}{1 - e^{-2\pi ik/p}} e^{c_1(N) + c_1(v(N, M)) + i\varphi(k) - 1)^{r+1} Td(N)[N] \prod_j \gamma(v(N, \theta_j))[N].$$
Proof. Similarly as in (3.6) in [5], we have
\[
\frac{1}{2} \eta_b = -\frac{1}{p} \sum_{k=1}^{p-1} \eta_b(g^k).
\]
Hence it follows from Theorem 2.4, Theorem 2.5 and Lemma 2.9 that
\[
F(g) = \frac{1}{p} \sum_{k=1}^{p-1} \sum_{N \in \mathbb{Z} \cap D(k)} \frac{1}{1 - e^{-2\pi ik/p}} \left( e^{\chi(N)} + e^{ij(N,N)} + (1)^{p-1} Td(N) \prod_{j} \Phi'(\chi(N, \theta_j))[N] \right)
\]
\[
+ \frac{1}{p} \int_X \text{Ch}(\xi_X) Td(X) - \frac{1}{p} \sum_{k=1}^{p-1} \text{Tr}(g^k|_{\ker D_y}) - \frac{1}{p} \sum_{k=1}^{p-1} \text{Index}(D_x, g^k)
\]
mod.\( \mathbb{Z} \). Here it follows from the same arguments as in Lemma 3.11 in [11] that
\[
\int_X \text{Ch}(\xi_X) Td(X) = 0
\]
and from Lemma 2.11 below that
\[
\sum_{k=1}^{p} \text{Index}(D_x, g^k) = 0 \mod. p.
\]
Therefore it suffices to show that
\[
\sum_{k=1}^{p} \frac{1}{2} \text{Tr}(g^k|_{\ker D_y}) = 0 \mod. p.
\]
Now, since the spin'(2n+1)-structure of \( Y = M \times S^1 \) comes from the U(n)-structure of \( M \), the spinor bundle \( E_Y \) splits into \( E_Y = E_Y^+ \oplus E_Y^- \) and \( D_y \) splits into \( D_y = D_y^+ \oplus D_y^- \) where
\[
D_y^+: \Gamma(E_y^+ \otimes \xi_y) \to \Gamma(E_y^- \otimes \xi_y)
\]
\[
D_y^- = (D_y^+)^*: \Gamma(E_y^- \otimes \xi_y) \to \Gamma(E_y^+ \otimes \xi_y)
\]
as in Lemma 2.6. Since \( g^k (1 \leq k \leq p-1) \) acts freely on \( Y \), it follows from the fixed point formula that
\[
\text{Index}(D_y^+ g^k) = \text{Tr}(g^k|_{\ker D_y^+}) - \text{Tr}(g^k|_{\ker D_y^-}) = 0
\]
for any \( 1 \leq k \leq p-1 \). Moreover, since the dimension of \( Y \) is odd, it follows as in Lemma 2.6 that
\[
\text{Index}(D_y^+) = \text{Tr}(g|_{\ker D_y^+}) - \text{Tr}(g|_{\ker D_y^-}) = 0.
\]
Hence it follows from Lemma 2.11 below that
This completes the proof.

**Lemma 2.1.** For any finite dimensional $\mathbb{Z}_p$-module $V$ where $\mathbb{Z}_p = \langle g \rangle$, we have

$$\sum_{k=1}^{p} \text{Tr}(g^k|_{\text{ker} D_V}) = 0 \mod p.$$

Proof. Apply the next (2.12) to the eigenvalues $\lambda_j (1 \leq j \leq \dim V)$ of $g|_V$.

\begin{equation}
\lambda^p = 1 \Rightarrow \sum_{k=1}^{p} \lambda^k = 0 \mod p.
\end{equation}

3. $F$ of Kähler surfaces with positive first Chern class

It is an immediate consequence of Theorem 1.6 and a known fact for $f$ (cf. [8, p100]) that $F$ does not vanish for the blowing-up of $CP^2$ at one or two points. Here, however, we compute $F$ of those complex manifolds as examples of Theorem 2.10. First, let $M$ be the surface obtained from $CP^2$ by blowing up one point $[1:0:0]$ where $[z_0:z_1:z_2]$ is the homogeneous coordinate on $CP^2$. Let $g$ be an element of $A(M)$ which is naturally induced by the element of $A(CP^2) = PGL(3; \mathbb{C})$ represented by

$$
\begin{pmatrix}
1 \\
\alpha \\
\alpha 
\end{pmatrix}
$$

where $\alpha = e^{2\pi i/p}$ for an integer $p \geq 2$. Then the fixed point set $\Omega(k) \subset M$ of $g^k$-action $(1 \leq k \leq p - 1)$ is independent of $k$ and is equal to the disjoint union of the exceptional divisor $E$ over $[1:0:0]$ and the hyperplane $H$ defined by $z_0 = 0$. Here the normal bundle $v(E,M)$ is equal to the tautological line bundle $J$ and the normal bundle $v(H,M)$ is equal to its dual $J^*$. $g^k$ acts on $J$ via multiplication by $\alpha^k$ and on $J^*$ via multiplication by $\alpha^{-k}$. Let

$$u \in H^2(E) = H^2(CP^1) = \mathbb{Z}, \quad v \in H^2(H) = H^2(CP^1) = \mathbb{Z}$$

be positive generators such that $u[E] = 1$ and $v[H] = 1$ where $[E]$, $[H]$ denote the
fundamental cycles. Then we have \( c_1(E) = 2u \) and \( c_1(H) = 2v \) and hence we have
\[
Td(E) = 1 + u, \quad Td(H) = 1 + v.
\]
Furthermore, since
\[
c_1(\nu(E, M)) = c_1(J) = -u, \quad c_1(\nu(H, M)) = c_1(J^*) = v,
\]
we have, by setting \( \theta = 2\pi k/p \),
\[
\psi'(\nu(E, \theta)) = \frac{1}{1 - \alpha^{-k}} + \frac{\alpha^{-k}}{(1 - \alpha^{-k})^2u}, \\
\psi'(\nu(H, \theta)) = \frac{1}{1 - \alpha^k} - \frac{\alpha^k}{(1 - \alpha^k)^2v}.
\]
Thus it follows from Theorem 2.10 that
\[
F(g) = \frac{1}{p} \sum_{k=1}^{p-1} \frac{1}{1 - \alpha^{-k}}(\alpha^k u - 1)^3(1 + u)(\frac{1}{1 - \alpha^{-k}} + \frac{\alpha^{-k}}{(1 - \alpha^{-k})^2u})[E] \\
+ \frac{1}{p} \sum_{k=1}^{p-1} \frac{1}{1 - \alpha^{-k}}(\alpha^{-k} v - 1)^3(1 + v)(\frac{1}{1 - \alpha^k} - \frac{\alpha^k}{(1 - \alpha^k)^2v})[H] \\
= \frac{1}{p} \sum_{k=1}^{p-1} \{\alpha^k(\alpha^k - 1) + 4\alpha^k u\}[E] \\
+ \frac{1}{p} \sum_{k=1}^{p-1} \{\alpha^{-k}(1 - \alpha^{-k}) + (2\alpha^{-k} - 10\alpha^{-2k})v\}[H] \\
= \frac{1}{p} \sum_{k=1}^{p-1} (4\alpha^k u + 2\alpha^{-k} - 10\alpha^{-2k})
\]
Now it follows from (2.12) that
\[
\sum_{k=1}^{p-1} \alpha^{jk} = -1 \mod p \quad \text{for any integer } j.
\]
Hence it follows that
\[
F(g) = \frac{1}{p} (-4 - 2 + 10) = \frac{4}{p} \mod Z.
\]
In particular, \( F(g) \neq 0 \) if \( p \neq 2, 4 \).

Secondly, let \( M \) be the surface obtained from \( CP^2 \) by blowing up two points \([1:0:0], [0:1:0]\) and \( \pi: M \to CP^2 \) the canonical projection. Let \( g \) be an element of \( A(M) \) which is naturally induced by the element of \( A(CP^2) \) represented by
where $\alpha = e^{2\pi i/p}$ for an odd integer $p \geq 3$. Then the fixed point set $\Omega(k) \subset M$ of $g^k$-action ($1 \leq k \leq p-1$) is independent of $k$ and is equal to the disjoint union of five points $p_1, p_2, p_3, p_4, p_5$ where $p_1 = \pi^{-1}([0:0:1]), p_2 = \pi^{-1}([1:0:0])$ is the point in $M$ defined by the line $z_1 = 0$ through the point $[1:0:0]$ in $CP^2$, $p_3 = \pi^{-1}([1:0:0])$ is the point in $M$ defined by the line $z_2 = 0$ through the point $[1:0:0]$ in $CP^2$, $p_4 = \pi^{-1}([0:1:0])$ is the point in $M$ defined by the line $z_0 = 0$ through the point $[0:1:0]$ in $CP^2$ and $p_5 = \pi^{-1}([0:1:0])$ is the point in $M$ defined by the line $z_2 = 0$ through the point $[0:1:0]$ in $CP^2$. Let $T_j = g_{|}_{T_M}$ denote the transformation of the tangent space $T_M$ induced by $g$. Then we can see that

$$
T_1 = \begin{pmatrix} \alpha^{-2} \\ \alpha^{-1} \end{pmatrix}, \quad T_2 = \begin{pmatrix} \alpha^{-1} \\ \alpha^2 \end{pmatrix}, \quad T_3 = \begin{pmatrix} \alpha & 0 \\ 0 & \alpha \end{pmatrix}, \quad T_4 = \begin{pmatrix} \alpha^{-2} \\ \alpha \end{pmatrix}, \quad T_5 = \begin{pmatrix} \alpha^{-1} \\ \alpha^2 \end{pmatrix}.
$$

Now it follows from Theorem 2.10 that

$$
F(g) = \sum_{p, k=1}^{p-1} \frac{1}{1-\alpha_k} \alpha^{(j)k}(\alpha^{(l)k} - 1) \frac{1}{1-\alpha^{-r(j)k}} \frac{1}{1-\alpha^{-s(j)k}}
$$

where $\alpha^{(j)}, \alpha^{(l)}$ are the eigenvalues of $T_j$. Hence, by setting $\alpha^k = \beta$, we have

$$
F(g) = \sum_{p, k=1}^{p-1} P(\beta)
$$

where

$$
P(\beta) = \frac{1}{1-\beta^{-1}(\beta^{-3} - 1)} \frac{1}{1-\beta^2} \frac{1}{1-\beta} + \frac{1}{1-\beta^{-1}(\beta - 1)} \frac{1}{1-\beta^2} \frac{1}{1-\beta} + \frac{1}{1-\beta^{-1}(\beta^2 - 1)} \frac{1}{1-\beta} \frac{1}{1-\beta^{-1}} + \frac{1}{1-\beta^{-1}(\beta^{-1} - 1)} \frac{1}{1-\beta^2} \frac{1}{1-\beta} + \frac{1}{1-\beta^{-1}(\beta - 1)} \frac{1}{1-\beta^2} \frac{1}{1-\beta}.
$$
where \( Q(\beta) \) is a polynomial of \( \beta \) and \( R \in \mathbb{C} \). Here we can see that \( Q(1) = -8 \) and \( R = 4 \). Hence it follows from (2.12) that

\[
\sum_{k=1}^{p-1} Q(\beta) = 8 \mod p.
\]

Therefore it follows that

\[
(3.1) \quad F(g) = \frac{1}{p} \left( 8 + \frac{4}{\beta + 1} \right)
= \frac{1}{p} \left( 8 + \sum_{k=1}^{p-1} \left( 2 - 2i \tan \frac{k}{p} \right) \right)
= \frac{1}{p} \frac{2p + 6}{p} \mod \mathbb{Z}.
\]

Thus \( F(g) \neq 0 \) if \( p \neq 3 \).

Remark 3.2. Let \( g_1, g_2, g_3, \tau \) be the elements of \( A(M) \) which are naturally induced by

\[
\begin{pmatrix}
\alpha & 1 & 0 \\
1 & \alpha & 0 \\
1 & 1 & \alpha \\
\end{pmatrix},
\begin{pmatrix}
1 & \alpha & 0 \\
\alpha & 1 & 0 \\
1 & \alpha & 0 \\
\end{pmatrix},
\begin{pmatrix}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1 \\
\end{pmatrix},
\begin{pmatrix}
0 & 1 & 0 \\
1 & 0 & 0 \\
0 & 0 & 1 \\
\end{pmatrix},
\]

respectively. Then it follows immediately from (3.1) that

\[
(3.3) \quad F(g_2) + 2F(g_3) = \frac{6}{p} \mod \mathbb{Z}.
\]

Moreover it is clear that

\[
(3.4) \quad F(g_1) = F(\tau^{-1} g_1 \tau) = F(g_2),
F(g_1) + F(g_2) + F(g_3) = F(1) = 0.
\]

Using (3.3) and (3.4), we can obtain that

\[
(3.5) \quad F(g_1) = F(g_2) = -\frac{2}{p}, \quad F(g_3) = \frac{4}{p} \quad \text{if } p \neq 0 \mod 3.
\]
Now, let $M$ be a 2-dimensional Kähler manifold with $c_1(M) > 0$, which is classified as one of $M = \text{CP}^1 \times \text{CP}^1$, $\text{CP}^2$ or $\text{CP}^2(m)$ where $\text{CP}^2(m)$ denotes the surface obtained from $\text{CP}^2$ by blowing up $m$-points ($1 \leq m \leq 8$) in general position. (cf. [4, p.321]) Note that the complex structure of $\text{CP}^2(m)$ ($5 \leq m \leq 8$) depends on the position of the $m$-points. When $M = \text{CP}^1 \times \text{CP}^1$ or $\text{CP}^2$, $M$ clearly admits a K-E metric. When $M = \text{CP}^2(1)$ or $\text{CP}^2(2)$, as was seen in this section, there exists $g \in A_0(M)$ such that $F(g) \neq 0$ and hence $M$ does not admit any K-E metric. (cf. Theorem 1.3 and Theorem 1.6.) When $M = \text{CP}^2(m)$ ($3 \leq m \leq 8$), Tian-Yau [18],[19] proved recently that $M$ admits a K-E metric. Here we have the following.

**Theorem 3.6.** Let $M$ be a Kähler surface with $c_1(M) > 0$. Assume that the complex structure is generic in the sense of [14] when $M = \text{CP}^2(m)$ ($5 \leq m \leq 8$). Then $F$ does not vanish if and only if $M = \text{CP}^2(1)$ or $\text{CP}^2(2)$.

Proof. When $M = \text{CP}^2$, $F(g) = 0$ for any $g \in A(M)$ because $A(M)$ is connected and $f(X) = 0$ for any $X \in H(M)$. (cf. Theorem 1.3 and Theorem 1.6) When $M = \text{CP}^2(1)$ or $\text{CP}^2(2)$, as was seen in this section, there exists $g \in A_0(M)$ such that $F(g) \neq 0$. When $M = \text{CP}^1 \times \text{CP}^1$ or $\text{CP}^2(3)$, $F(g) = 0$ for any $g \in A_0(M)$ because $f(X) = 0$ for any $X \in H(M)$ (cf. [8, p.100]). Now we can see that $A(\text{CP}^1 \times \text{CP}^1)/A_0(\text{CP}^1 \times \text{CP}^1)$ is isomorphic to $Z_2$ and it follows from the Theorem in [14] that

$$A(\text{CP}^2(3)) = A_0(\text{CP}^2(3)) \cdot D(12),$$

$(D(12)$ denotes the dihedral group of order 12.)

$$A(\text{CP}^2(4)) = \text{symmetric group } S(5), \quad A(\text{CP}^2(5)) = \oplus^4 Z_2,$$

$$A(\text{CP}^2(6)) = \{1\}, \quad A(\text{CP}^2(7)) = Z_2, \quad A(\text{CP}^2(8)) = Z_2.$$

Hence it suffices to show that

(3.7) $F(g) = 0$ if the dimension of $M$ is 2 and the order of $g \in A(M)$ is 2.

Now fix any $g \in A(M)$ of order 2. Let $\Omega \subset M$ be the fixed point set of $g$, which consists of $g$-points $p_1, p_2, \ldots, p_q$ and $r$-curves $D_1, D_2, \ldots, D_r$. Then it follows from Theorem 2.10 that

(3.8) $F(g) = \frac{1}{4} \left\{ \sum_{s=1}^{q} \Phi(p_s) + \sum_{t=1}^{r} \Psi(D_t) \right\}$

where

$$\Phi(p_s) = (e^{c_1(p_s) + c_1(\nu(p_s,M))} + \nu - 1)^{\nu + 1} Td(p_s) \nu^{-\nu}(\nu(p_s,\nu)[p_s])$$

and

$$\Psi(D_t) = (e^{c_1(D_t) + c_1(\nu(D_t,M))} + \nu - 1)^{\nu + 1} Td(D_t) \nu^{-\nu}(\nu(D_t,\nu)[D_t]).$$
Now it is clear that $c_1(p_s) = c_1(v(p_s, M)) = 0$ and we have $e^{i\phi} = 1$ because $g$ acts on $K_M^{-1}|_{p_s}$ via multiplication by 1. Hence it follows that $\Phi(p_s) = 0$ for any $1 \leq s \leq q$. On the other hand, let $a, b$ denote $c_1(D_2), c_1(v(D_n, M))$, respectively. Then, we have $e^{i\phi} = -1$ because $g$ acts on $K_M^{-1}|_{D_n}$ via multiplication by $-1$ and moreover we have

$$e^{i\phi} = 1 + (a + b)$$

$Td(D_2) = 1 + \frac{1}{2} a$

$$\nu(v(D_n, M)) = \frac{1}{1 + e^{-b}} = \frac{1}{2} + b.$$

Hence it follows that

$$\Psi(D_2) = (-1 + (-1)(a + b) - 1)^2(1 + \frac{1}{2} a)(\frac{1}{2} + b[D_2])$$

$$= -8(a + b)[D_2] = 0 \mod 4 \quad (1 \leq t \leq r).$$

Thus it follows from (3.8) that $F(g) = 0$.

This completes the proof.

4. Other examples and some remarks

Now let $M \subseteq CP^{n+r}$ be a complete intersection of degree $(d_1, d_2, \cdots, d_r)$ defined by the simultaneous equations

$$a_1z_1^{d_1} + \cdots + a_{n+r}z_1^{d_1} = 0$$

$$a_2z_2^{d_2} + \cdots + a_{n+r}z_2^{d_2} = 0$$

$$\cdots$$

$$a_rz_r^{d_r} + \cdots + a_{n+r}z_r^{d_r} = 0$$

Assume that $\{d_1, d_2, \cdots, d_r\}$ has the greatest common divisor $p \geq 2$. Assume moreover that $a_j \neq 0$ for some $j$ and that $N = M \cap \{z_0 = 0\} \subseteq CP^{n+r-1}$ defined by

$$a_1z_1^{d_1} + \cdots + a_{n+r}z_1^{d_1} = 0$$

$$a_2z_2^{d_2} + \cdots + a_{n+r}z_2^{d_2} = 0$$

$$\cdots$$

$$a_rz_r^{d_r} + \cdots + a_{n+r}z_r^{d_r} = 0$$

is also a complete intersection in $CP^{n+r-1}$. Then $Z_p = \langle g \rangle$ acts on $M$ by

$$g \cdot [z_0 : z_1 : \cdots : z_{n+r}] = [az_0 : z_1 : \cdots : z_{n+r}]$$

where $\alpha = e^{2\pi i/p}$. 

Theorem 4.1. \( F(g) = 0 \) for any \( n, r \) and any \((d_1, d_2, \cdots, d_r)\).

Proof. The fixed point set \( \Omega \subset M \) of \( g^k \)-action \((1 \leq k \leq p - 1)\) is the hypersurface \( N = M \cap \{z_0 = 0\} \) in \( M \). Let \( L \) be the hyperplane bundle of \( CP^{n+r-1} \), which is the dual bundle of the tautological bundle of \( CP^{n+r-1} \). Set

\[
x = c_i(L|_N) \in H^2(N).
\]

Then \( x^{n-1}[N] = D \) and \( c_i(N) = (n + r - d)x \) where \( D = d_1d_2 \cdots d_r \) and \( d = d_1 + d_2 + \cdots + d_r \). Now, since \( TCP^{n+r-1}|_N = TN \oplus \bigoplus_{j=1}^{r} \otimes^d(L|_N) \),

it follows that

\[
Td(N) = \left( \frac{x}{1 - e^{-x}} \right)^{n+r} \prod_{j=1}^{r} \frac{1 - e^{-d_j x}}{d_j x}.
\]

Moreover, since \( TM|_N = TN \oplus (L|_N) \) and \( g^k \) acts on \( L|_N \) via multiplication by \( \alpha^k \), it follows that

\[
e^{\psi_1(N) + c_1(v(N, M)) + i\omega(k)} = \alpha^k e^{(n + r + 1 - d)x},
\]

\[
\psi(v(N, \theta_j)) = \frac{1}{1 - \alpha^{-k} e^{-x}}.
\]

Hence it follows from Theorem 2.10 that

\[
F(g) = -\sum_{p=1}^{n-1} \frac{1}{1 - \alpha^{-k}} \{\alpha^k e^{(n + r + 1 - d)x} - 1\}^{n+1} \left( \frac{x}{1 - e^{-x}} \right)^{n+r} \prod_{j=1}^{r} \frac{1 - e^{-d_j x}}{d_j x} \frac{1}{1 - \alpha^{-k} e^{-x}}[N].
\]

Thus we have

\[
F(g) = \frac{D}{p} \sum_{k=1}^{p-1} C(k)
\]

where \( C(k) \) denotes the \( x^{n-1} \)-coefficient of

\[
\frac{1}{1 - \alpha^{-k}} \{\alpha^k e^{(n + r + 1 - d)x} - 1\}^{n+1} \left( \frac{x}{1 - e^{-x}} \right)^{n+r} \prod_{j=1}^{r} \frac{1 - e^{-d_j x}}{d_j x} \frac{1}{1 - \alpha^{-k} e^{-x}} \in C[[x]].
\]

Now,

\( x^{n-1} \)-coefficient of

\[
D \{\alpha^k e^{(n + r + 1 - d)x} - 1\}^{n+1} \left( \frac{x}{1 - e^{-x}} \right)^{n+r} \prod_{j=1}^{r} \frac{1 - e^{-d_j x}}{d_j x} \frac{1}{1 - \alpha^{-k} e^{-x}}
\]
\[ = x^{-1}\text{-coefficient of} \]
\[
\alpha^k e^x \left( \alpha^k e^{(n+r+1-d)x} - 1 \right)^{n+1} \left( \frac{1}{1-e^{-x}} \right)^{n+r} \prod_{j=1}^{r} \left( 1 - e^{-d_j x} \right)
\]
\[
= \frac{1}{2\pi i} \oint_{C(z)} \frac{\alpha^k (x^2 e^{(n+r+1-d)x} - 1)^{n+1} (e^x)^{n+r}}{\alpha^k e^x - 1} \left( \frac{e^x}{e^x - 1} \right)^{n+r} \prod_{j=1}^{r} \left( \frac{(e^{d_j x} - 1)}{(e^{d_j x})} \right) e^x dz
\]
(where \( C(z) \) is a sufficiently small counterclockwise loop around the origin)

\[ = \frac{1}{2\pi i} \oint_{C(u)} \frac{\alpha^k (x^2 (u+1)^{n+r+1-d} - 1)^{n+1} (u+1)^{n+r}}{\alpha^k (u+1) - 1} u^{n+r} \prod_{j=1}^{r} \frac{u(d_j + h_j(u))}{(u+1)^{d_j - 1}} du
\]
(via the substitution \( u = e^x - 1 \), where \( C(u) \) is a counterclockwise loop around the origin)

\[ = u^{-1}\text{-coefficient of} \]
\[
\frac{\alpha^k (x^2 (u+1)^{n+r+1-d} - 1)^{n+1} (u+1)^{n+r-d}}{\alpha^k (u+1) - 1} \prod_{j=1}^{r} \left( u(d_j + h_j(u)) \right)
\]
(where \( h_j(u) \) is an integral polynomial of order \( \geq 1 \) in \( u \))

\[ = u^{n-r-1}\text{-coefficient of} \]
\[
\frac{\alpha^k (x^2 (u+1)^{n+r+1-d} - 1)^{n+1} (u+1)^{n+r-d}}{\alpha^k (u+1) - 1} \prod_{j=1}^{r} (d_j + h_j(u)).
\]

Set
\[
P(u) = (u+1)^{n+r-d} \prod_{j=1}^{r} (d_j + h_j(u))
\]
\[
Q(u) = \sum_{k=1}^{p-1} \frac{1}{\alpha^{-k}} \frac{\alpha^k (x^2 (u+1)^{n+r+1-d} - 1)^{n+1}}{\alpha^k (u+1) - 1}.
\]

Then it follows from the calculation above that it suffices to show that the \( u^{n-r-1}\text{-coefficient of} \( P(u)Q(u) \) is 0 mod.\( p \). Note that \( P(u), Q(u) \) can be expanded to convergent power series around \( u = 0 \). Note moreover that \( P^{(s)}(0) \) is an integral multiple of \( s! \) because \( P(u) \) can be expanded to a convergent power series with integral coefficients.

Now set
\[
\Phi(x,u) = \{ x(u+1)^{n+r+1-d} - 1 \}^{n+1}.
\]
Then we can see that, for any integer \( s \) with \( 0 \leq s \leq n + 1 \),

\[
\frac{\partial^s}{\partial u^s} \Phi|_{u=0} = s! \phi_s(x)(x-1)^{n+1-s}
\]

for some integral polynomial \( \phi_s \).

Actually it is clear that

\[
\frac{\partial^s}{\partial u^s} \Phi|_{u=0} = \mu_s(x)(x-1)^{n+1-s}
\]

for some integral polynomial \( \mu_s \). On the other hand, since \( \Phi \) can be expanded to a convergent power series of \( u \) around \( u=0 \) whose coefficients are integral polynomials of \( x \), it follows that

\[
\frac{\partial^s}{\partial u^s} \Phi|_{u=0} = s! \nu_s(x)
\]

for some integral polynomial \( \nu_s \). Hence it follows that

\[
\mu_s(x)(x-1)^{n+1-s} = s! \nu_s(x).
\]

Since the top order term of \((x-1)^{n+1-s}\) is equal to 1, it follows from (4.3) that

\[
\mu_s(x) = s! \phi_s(x)
\]

for some integral polynomial \( \phi_s \),

which implies (4.2).

Now, for \( m \leq n-1 \), we have

\[
Q^{(m)}(0) = \sum_{k=1}^{p-1} \left( \sum_{s=0}^{m} \binom{m}{s} (x^k(u+1)-1)^{m-s}(x^k(u+1)^{n+s+1-d}-1)^{s+1}(0)ight) = \sum_{k=1}^{p-1} \sum_{s=0}^{m} \binom{m}{s} (-1)^{m-s} s! \phi_s(x^k(x^k-1))^{n+1-s}
\]

\[
= m! \sum_{k=1}^{p-1} \sum_{s=0}^{m} (-1)^{m-s} s! \phi_s(x^k(x^k-1))^{n+1-s}.
\]

Hence it follows from the fact (See (2.12).)

\[
\sum_{k=1}^{p-1} \Psi(x^k) = -\Psi(1) \mod p
\]

that \( Q^{(m)}(0) \) is an integral multiple of \( p \cdot m! \) if \( m \leq n-2 \) and is equal to an integral multiple of \( (n-1)! \) if \( m = n-1 \). Therefore it follows that

\[
\frac{1}{(n-1)!} (PQ)^{n-1}(0)
\]
\[
\frac{1}{(n-1)!} \left\{ P(0)Q^{(n-1)}(0) + \sum_{m=0}^{n-2} \binom{n-1}{m} P^{(n-1-m)}(0) Q^{(m)}(0) \right\}
= P(0)Q^{(n-1)}(0) + \sum_{m=0}^{n-2} \frac{P^{(n-1-m)}(0) Q^{(m)}(0)}{(n-1)!} \frac{m!}{m!}
\]
is equal to 0 mod.\(p\) because \(P(0)\) is equal to \(d_1 d_2 \cdots d_r\) which is an integral multiple of \(p\). Thus it follows that
\[
u^{n-1}\text{-coefficient of } P(u)Q(u) = 0 \text{ mod. } p.
\]
This completes the proof.

**Remark 4.4.** Let \(M\) be the Fermat cubic surface
\[
M: z_0^3 + z_1^3 + z_2^3 + z_3^3 = 0 \text{ in } \mathbf{C}P^3
\]
and
\[
 g \cdot [z_0:z_1:z_2:z_3] = [e^{2\pi i/3} z_0:z_1:z_2:z_3].
\]
Then \(A(M)\) is a finite group generated by \(g\) and the transposition of coordinates whose order is 2. Hence it follows from Theorem 4.1 and (3.7) that
\[
F(g) = 0 \text{ for any } g \in A(M).
\]
Note that the Fermat cubic surface is isomorphic to the six points blowing-up of \(\mathbf{C}P^2\) with non-generic complex structure in the sense in section 3.

**Remark 4.5.** In [16] certain kinds of complete intersections including the case that \(r = 1, \frac{n+1}{2} \leq d_1 \leq n+1\) are shown to admit K-E metrics, and no example of a complete intersection which does not admit any K-E metric is known.

**Remark 4.6.** Using the \(\otimes^{n+1}(TM - \mathcal{E})\)-valued spin\(^c\)-Dirac operators (where \(\mathcal{E}\) denotes the trivial bundle \(M \times \mathbf{C}^n\)) instead of the \(\otimes^{n+1}(K_M^{-1} - \mathcal{E})\)-valued spin\(^c\)-Dirac operators, we can obtain a formula similar to Theorem 2.10.

**Remark 4.7.** We can see that the lifted Futaki invariant \(F\) is interpreted as a "holonomy" of a \(\otimes^{n+1}(TM - \mathcal{E})\)-valued spin\(^c\)-Dirac operator (cf. [20]).
