SFKs	Src family tyrosine kinases
TGF-β	Transforming growth factor-β
TIGR	Trabecular meshwork-induced glucocorticoid response

TBS-T	Tris buffered saline with Tween-20
tPA	Tissue plasminogen activator

Abstract

Glaucoma, a progressive and irreversible optic neuropathy, is one of the leading causes of vision impairment worldwide. Elevation of intraocular pressure (IOP) due to TGF-β–induced dysfunction of the trabecular meshwork is a risk factor for glaucoma, but the underlying molecular mechanisms remain elusive. Here, I show that Src kinase is involved in TGF-β–induced IOP elevation. I observed that dasatinib, a potent Src family kinase inhibitor, suppressed TGF-β2–induced IOP elevation in rat eyes. Mechanistic analyses in human trabecular meshwork cells showed that TGF-β2 activated Src signaling and concomitantly increased cytoskeletal remodeling, cell adhesion, and extracellular matrix (ECM) accumulation. Src was activated via TGF-β2-induced upregulation of the Src scaffolding protein CasL, which mediates the assembly of focal adhesions, cytoskeletal remodeling, and ECM deposition. Activation of Src suppressed the expression of tissue plasminogen activator, thereby attenuating ECM degradation. Furthermore, dasatinib ameliorated TGF-β2-induced changes in the contractile and adhesive characteristics of trabecular meshwork cells, and ECM deposition. These findings suggest that Src activity is involved in TGF-β–induced IOP elevation and identify Src signaling as a potential therapeutic target in glaucoma.

Introduction

Glaucoma, a progressive and irreversible optic neuropathy, is one of the leading causes of blindness worldwide (Bourne et al., 2018; Congdon et al., 2004; Yamada et al, 2010). A retinal ganglion cell (RGC) is a type of retinal neuron (Fig. 1A). The retinal nerve fiber layer is formed by RGC axons and the optic nerve, which is a bundle of retinal nerve fibers, connects to the brain (Fig. 1B). In glaucoma, apoptotic death of RGCs and damage of the optic nerve cause structural changes (retinal nerve fiber defects, thinning of ganglion cell layer, and optic nerve head cupping, etc.) in the retina and optic nerve. The visual field is impaired as optic nerve damage progresses and some glaucoma patients develop blindness. Simulation of visual field defects in glaucoma patients is shown in Fig. 1C. The number of glaucoma patients is increasing and people with blindness due to glaucoma will reach 11.2 million by 2020 worldwide (Quigley and Broman, 2006).

Although the pathogenesis of glaucoma is not well understood, elevated intraocular pressure (IOP) is a risk factor that contributes to progression of visual field defects. Consistent with this, reduction of IOP suppresses visual field defects (Garway-Heath et al., 2015; Heijl et al., 2002), and reduction of IOP is currently the only evidence-based treatment for glaucoma. The mechanical theory is proposed as a mechanism to explain visual field defects caused by elevated IOP. The mechanical theory suggests that elevated IOP compresses RGC axons, resulting in the obstruction of anterograde and retrograde axonal transport. Impaired axonal transport leads to depletion of factors to maintain RGC homeostasis such as brain derived neurotrophic factor and induces RGC death (Pease et al., 2000; Quigley et al., 2000). Since visual impairment due to glaucoma is irreversible, it is important to detect pathological signs of glaucoma at early stages. Once diagnosed with glaucoma, the patients require long term IOP-lowering therapy such as medicinal treatment, laser therapy, or surgery and the goal of glaucoma therapy is to maintain visual function. Several drugs to decrease IOP have been used for treatment of glaucoma. For instance, prostaglandin analogues, β-blockers, carbonic anhydrase

inhibitors, α2-adrenoceptor agonist, and rho kinase inhibitors are available for glaucoma therapy. Of these, prostaglandin analogues are frequently used as first-line due to their efficacy and fewer systemic side effects. Although β-blockers are also first line therapy, their efficacy is consider to be inferior to that of prostaglandin analogues. However, these approved drugs are not necessarily effective in all glaucoma patients. For example, a previous report showed that approximately 20% and 30% of patients were non-responder in treatment with latanoprost, (prostaglandin analogue) and timolol (β-blocker), respectively (Camras and Hedman, 2003). Furthermore, side effects related to mechanism of action restrict the clinical use of these drugs in certain cases. Conjunctival hyperemia and iris pigmentation are well-known side effects of prostaglandin analogues. Beta-blockers may induce systemic side effects such as bradycardia and bronchoconstriction. Therefore, new IOP-lowering drugs with novel mechanism of action are desired.

Glaucoma is classified into open-angle and angle-closure glaucoma (Fig. 2). The angle between iris and cornea is open in open-angle glaucoma. In contrast, the angle is usually blocked by iris in angle-closure glaucoma. Furthermore, both open-angle and angle-closure glaucoma are divided into primary and secondary glaucoma. Secondary glaucoma is the glaucoma caused by other eye disorders or medical treatment such as glucocorticoids. Primary open-angle glaucoma (POAG) is the most common form of glaucoma and accounts for approximately 75% of all glaucoma cases (Iwase et al., 2004; Quigley and Broman, 2006; Yamamoto et al., 2005). Normal tension glaucoma (NTG) is thought to be a type of open angle glaucoma in which damage occurs to the optic nerve in the normal range of IOP (lower than 21 mmHg). Although the pathogenesis of NTG is still unknown, lowering IOP is effective in NTG as well (Collaborative Normal-Tension Glaucoma Study Group, 1998).

IOP, a risk factor of glaucoma, is regulated by the balance between the production and drainage of aqueous humor. The aqueous humor is formed in the ciliary body and drained through the trabecular meshwork and the uveoscleral pathway (Fig. 3A). In humans, the aqueous humor is mainly drained through the trabecular meshwork, which is located in the iridocorneal angle, into Schlemm's

canal. Aqueous outflow via the trabecular meshwork outflow increases with the elevation of IOP (IOP-dependent outflow). IOP elevation is thought to be caused by elevated resistance to the outflow of aqueous humor due to dysfunction of the trabecular meshwork in POAG (Johnson, 2006; Roy Chowdhury et al., 2015). Extracellular matrix (ECM) is a non-cellular substance that fills extracellular space as a supportive framework. ECM is involved in various cellular responses such as proliferation, migration, differentiation, and phenotypic expression of cells by acting as a scaffold. ECM is also known as a mediator of signal transduction. ECM proteins such as fibronectin and collagen IV are enriched in the trabecular meshwork to maintain its function (Acott and Kelley, 2008). Deposition of abnormal ECM or modulation of cytoskeleton in the trabecular meshwork may be responsible for increased resistance to outflow (Lutjen-Drecoll et al., 1981; Read et al., 2007; Vranka et al., 2015). However, the molecular mechanisms responsible for increasing outflow resistance remain unclear.

Trabecular meshwork consists of three cell layers as shown in Fig. 3B. Resistance to outflow of aqueous humor is thought to be generated in inner wall of Schlemm's canal and juxtacanalicular connective tissue (JCT) consisted of cells and ECM (Ethier et al., 1986). In the normal trabecular meshwork, the outflow of the aqueous humor appear to be regulated by turnover of ECM in response to mechanical stretch of JCT induced by IOP elevation, resulting in maintaining IOP homeostasis (Bradley et al., 1998; Bradley et al., 2001). Therefore, dysregulation of trabecular meshwork cells may induce abnormal deposition of ECM, leading to IOP elevation. Contraction and relaxation of the trabecular meshwork is also thought to regulate IOP (Nakajima et al., 2005; Wiederholt et al., 2000). Moreover, the number of trabecular meshwork cells decreases in POAG patients and IOP homeostasis is lost by death of trabecular meshwork cells with treatment of saponin in an enucleated human anterior segment culture model (Abu-Hassan et al., 2015; Alvarado et al., 1984). These indicate that trabecular meshwork cells play crucial roles in regulation of outflow of aqueous humor and IOP.

Trabecular meshwork cells used in this study were isolated from the juxtacanalicular and corneoscleral regions of human eye. I obtained trabecular meshwork cells from ScienCell Research

Laboratories, since they were used in several studies concerned with glaucoma (Cavet et al., 2015; Kalouche et al., 2016; Inoue-Mochita et al., 2018; Matsuda et al., 2015; Tellios et al., 2017). Increased expression of myocilin, a secreted glycoprotein (previously known as TIGR), induced by glucocorticoids is a reliable marker for trabecular meshwork cells, because the response is not observed in other cells around the trabecular meshwork (Keller et al., 2018). Although exact function of myocilin remains unclear (Nguyen et al., 1998), it is considered as one of the causative genes for POAG due to significant mutations (3 - 5%) in adult POAG populations (Allingham et al., 2009).

Transforming growth factor-β (TGF-β) is a multifunctional growth factor that regulates cell growth, differentiation, adhesion, migration, ECM production, epithelial–mesenchymal transition (EMT), and malignant progression. TGF-β has three isoforms (TGF-β1, β2, and β3) that commonly bind to serine/threonine kinase receptors (type I and type II). Upon ligand binding, the activated type II receptor phosphorylates the GS domain of the type I receptor, which in turn activates downstream signaling pathways, such as Smad phosphorylation (Heldin et al., 1997; Itoh and ten Dijke, 2007). TGF-β also regulates the function of trabecular meshwork cells (Wordinger et al., 2007; Yu et al., 2015), and its dysregulation is implicated in the etiology of POAG. For instance, the expression level of TGF-β2, but not TGF-β1 or TGF-β3, in aqueous humor is higher in POAG patients than in controls (Agarwal et al., 2015; Ochiai and Ochiai, 2002; Yoneda et al., 2007). In an enucleated human anterior segment culture model, treatment with TGF-β2 decreases the outflow of aqueous humor via the trabecular meshwork, suggesting that TGF-β2 plays an important role in the regulation of IOP (Gottanka et al., 2004). Moreover, IOP elevation induced by the injection of TGF-β2 into the rat eyes caused the death of retinal ganglion cells which are injured in glaucoma (Hill et al., 2015).

Src family kinases (SFKs) are non-receptor tyrosine kinases that were the first proto-oncogene products to be identified (Jove and Hanafusa, 1987). SFKs include c-Src, c-Yes, Fyn, c-Fgr, Lyn, Hck, Lck, and Blk. SFKs are expressed in various types of cells and functional redundancy among SFKs is known (Thomas and Brugge, 1997). SFKs regulate cellular functions such as

cytoskeleton remodeling, cell adhesion, and cell migration (Huveneers and Danen, 2009; Parsons and Parsons, 2004; Thomas and Brugge, 1997). Dysregulation of SFKs is associated with various diseases, including cancer and fibrosis (Massip Copiz and Santa Coloma, 2016; Wang and Zhuang, 2017; Yeatman, 2004). Consistent with this, dasatinib, a potent SFK inhibitor, is prescribed for treatment of acute lymphoblastic leukemia or chronic myeloid leukemia. SFK activity is strictly regulated by tyrosine phosphorylation at specific sites. In the resting state, Src is phosphorylated at Tyr529 (in human) (Brown and Cooper, 1996; Cooper et al., 1986) by C-terminal Src kinase (Csk) (Nada et al., 1991; Nada et al., 1993; Okada, 2012), causing it to adopt an inactive conformation. In response to stimulation by extracellular signals, such as ECMs and growth factors (Ha et al., 2008; Kaplan et al., 1995; Kypta et al., 1990), Src is activated via autophosphorylation at Tyr418 (in human) (Fig. 4). Src functions as a component of the focal adhesion complex, which connects extracellular ECM to actin fibers, by phosphorylating other components such as focal adhesion kinase (FAK) and paxillin (Harte et al., 1996; Schaller, 2001). Previous study revealed that Src was activated during TGF-β–induced EMT and that its activation promoted mesenchymal features, e.g., cell adhesion, migration and ECM production, which are tightly associated with cancer malignancy (Komiya et al., 2016; Miyazono, 2009). In trabecular meshwork cells, TGF-β can also promote cytoskeletal remodeling, cell adhesion, and ECM production (Wecker et al., 2013; Wordinger et al., 2007; Yu et al., 2015), similarly to epithelial cells. Therefore, I hypothesized that SFKs may contribute to TGF-β2–induced IOP elevation in POAG as well. In this study, I analyzed the role of SFKs in TGF-β signaling in human primary trabecular meshwork cells, focusing on Src as a representative SFK. I show that Src is activated by TGF-β2, and that it may contribute to TGF-β‑induced IOP elevation by promoting the contractile and adhesive properties of trabecular meshwork cells, as well as ECM deposition.

Materials and methods

Reagents and antibodies

SD-208 and dexamethasone were purchased from Wako Pure Chemical Industries. Dasatinib was purchased from BioVision. TGF-β2 was purchased from Cell Signaling Technology. Rhodamine-conjugated phalloidin was purchased from Cytoskeleton. Primary antibodies used were rabbit anti-GAPDH (1:5000–1:10000; 3700S; Santa Cruz Biotechnology), rabbit anti-Fyn (1:1000; sc-16; Santa Cruz Biotechnology), mouse anti-phosphotyrosine (4G10; 1:2000–1:5000; 05-1050; Millipore), rabbit anti-CSK (1:000; 4980S; Cell Signaling Technology), rabbit anti-FAK (1:1000; 13009S; Cell Signaling Technology), rabbit anti-paxillin pY118 (1:1000; 2541S; Cell Signaling Technology), mouse anti-CasL (1:1000; 4044S; Cell Signaling Technology), rabbit anti-Src (1:1000; 2123S; Cell Signaling Technology), mouse anti-Src (1:1000; 2110S; Cell Signaling Technology), rabbit anti-Abl (1:1000; 2862S; Cell Signaling Technology), rabbit anti-Yes (1:1000; 3201S; Cell Signaling Technology), rabbit anti-FAK pY576 (1:10000; ab76244; Abcam), rabbit anti-N-Cadherin (1:5000; ab76011; Abcam), rabbit anti-paxillin (IB 1:5000, IHC 1:250; ab32084; Abcam), rabbit anti-fibronectin (1:250; ab45688; Abcam), and rabbit anti-Src pY418 (IB 1:2000–1:5000, IHC 1:50; 44-660G; Thermo Fisher Scientific). Horseradish peroxidase–conjugated anti-mouse or rabbit IgG secondary antibodies were purchased from Cell Signaling Technology or Jackson Immuno Research Laboratories. Alexa Fluor 488–conjugated anti-rabbit IgG antibodies were purchased from Thermo Fisher Scientific.

Cell culture

Primary human trabecular meshwork cells (Lot No.3423) were purchased from ScienCell Research Laboratories. The HepG2 cell line was purchased from the American Type Culture Collection. Cells were cultured in Dulbecco’s modified Eagle’s medium (DMEM) supplemented with 10% fetal bovine

serum (FBS) at 37°C in a 5% CO_2 incubator; trabecular meshwork cells were cultured on poly-L-lysine–coated plates. For experiments, cells were treated with reagents diluted in serum-free DMEM.

Plasmid and siRNA

cDNAs encoding Src and CasL were inserted into pCAG-Hyg (Wako Pure Chemical Industries) and pmaxCloning (Lonza), respectively. pmaxGFP was purchased from Lonza. Negative-control siRNA (No.1), CSK siRNA (#1: s3612, #2: s223346), and CasL siRNA (#1: s9428, #2: s9429) were purchased from Ambion. Plasmids and siRNAs were transfected into trabecular meshwork cells using Nucleofector 4D (Lonza) and the P5 Primary Cell 4D-Nucleofector X Kit (Lonza). Nucleofection was performed using program DY138 after plasmids (1 μg) or siRNAs (2 μM) were added to cells (5×10^5 cells/100 μL) resuspended in the solution provided in the kit. After nucleofection, DMEM containing 10% FBS was added to the nucleofected cells. The next day, medium was changed to DMEM without FBS. Plasmids were transfected into HepG2 cells using Lipofectamine 3000 (Thermo Fisher Scientific).

RT-PCR and microarray analysis

Total RNA was prepared using ISOGEN with Spin Column (Nippon Gene) or RNeasy Mini Kit (QIAGEN). cDNA was synthesized from total RNA using the PrimeScript RT Reagent Kit (TaKaRa-Bio). Quantitative polymerase chain reaction was performed using SYBR Premix Ex Taq II (TaKaRa-Bio), the CFX-96 real time PCR detection system (Bio-Rad Laboratories), and primers listed in Table 1. For microarray analysis, two-color Agilent Array analysis (SurePrint G3 Human GE 8× 60K Ver3.0) was carried out by TaKaRa-Bio. RNA from two samples in each group were mixed and used for microarray analyses.

Immunoblotting and immunoprecipitation

Cells were washed with Dulbecco phosphate-buffered saline (D-PBS) and lysed with ODG buffer (50 mM Tris–HCl, pH 7.4, 150 mM NaCl, 1 mM EDTA, 1% NP-40, 5% glycerol, 2% n-octyl-β-D-glucoside) with a protease inhibitor cocktail containing 1 mM 4-(2-Aminoethyl)benzenesulfonyl Fluoride Hydrochloride, 0.8 μg/mL aprotinin, 15 μM E-64, 20 μM Leupeptin Hemisulfate, 50 μM Pepstatin, and 10 μM Pepstatin A (Nacalai Tesque) and a phosphatase inhibitor cocktail containing imidazole, tetra-sodium ethylenediaminetetraacetate, sodium orthovanadate, β-glycerophosphoric acid disodium salt, sodium (+)-tartrate dihydrate, sodium fluoride, and disodium molybdate (VI) dihydrate (undisclosed concentration, Nacalai Tesque). Immunoprecipitation was performed with the Dynabeads–Protein A or G Immunoprecipitation Kit (Thermo Fisher Scientific). Equal amounts of protein were subjected to sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-PAGE) and transferred to polyvinylidene difluoride membrane using the iBlot2 System (Thermo Fisher Scientific). Membranes were incubated with primary antibodies after blocking with BSA, ECL Blocking agent (GE Healthcare), or Bullet Blocking One for Western Blotting (Nacalai Tesque). After washing with TBS-T (25 mM Tris, 0.15 M NaCl, 0.05% Tween-20, pH 7.5), membranes were incubated with HRP-conjugated secondary antibody, and then washed with TBS-T. After detection with phospho-specific antibodies, the same blots were stripped and reprobed with total antibodies. Antibodies were diluted in TBS-T. Signals visualized with ImmunoStar LD were recorded on an ImageQuant LAS 4000 (GE Healthcare), and band intensity was quantified using ImageQuant TL software (GE Healthcare). Representative immunoblotting images obtained from at least three independent experiments are shown.

LC-MS/MS analysis

Lysates prepared from trabecular meshwork cells treated with TGF-β2 were immunoprecipitated using anti-phosphotyrosine antibody (4G10) and the Dynabeads–Protein G Immunoprecipitation Kit

(Thermo Fisher Scientific). Protein samples were separated by SDS-PAGE. After visualization by silver staining, proteins were excised from the gel fragments. Digested samples were analyzed by nanocapillary reversed-phase LC-MS/MS using a C18 column (φ75 mm) on a nano LC system coupled to an ESI-MS/MS (LTQ Orbitrap Velos, Thermo Fisher Scientific). Direct-injection data-dependent acquisition was performed using one MS channel for every three MS/MS channels and dynamic exclusion for selected ions. Proteins were identified by database searching using Mascot Daemon (Matrix Science).

Immunocytochemistry

Cells were fixed with 10% formalin neutral buffer solution for 10 min at room temperature. After washing with TBS-T, samples were permeabilized with 0.03% digitonin for 15 min, and blocked with Blocking One (Nacalai Tesque) or Blocking One-P (Nacalai Tesque). Cells were incubated with primary antibodies overnight at 4°C, followed by incubation with Alexa Fluor 488–conjugated secondary antibody and rhodamine–phalloidin for 1 h at room temperature. Antibodies and phalloidin were diluted in TBS-T containing 5% Blocking One or Blocking One-P. Samples were mounted with 50% glycerol after washing with TBS-T. Images were taken on a BIOREVO BZ-9000 fluorescence microscope (KEYENCE). Representative images obtained from at least three independent experiments are shown.

Animal experiments

All procedures were performed in accordance with the approved standard Guidelines for Animal Care and Use of Otsuka Pharmaceutical Co. Ltd under approval of the Animal Experiment Committee of Otsuka Pharmaceutical Co. Ltd (approved number: 16-0431). Male Brown Norway rats (7–8 weeks old) were purchased from Charles River Laboratories, Japan. Rats were anesthetized with pentobarbital sodium (50 mg/kg, i.p.), and oxybuprocaine hydrochloride 0.4% (ocular instillation).

Test solutions (volume, 3.5 μL; vehicle, 5.25 ng/eye TGF-β2, or 5.25 ng/eye TGF-β2 + 35 pmol/eye dasatinib) were injected into the anterior chamber with a 32G needle and Hamilton syringe, after injection of air to avoid leakage of the test solutions. Injection was performed twice a week until day 16. IOP was measured with a TonoLab tonometer (Icare) in the conscious state between 8:30AM and 11:00AM. Oxybuprocaine hydrochloride 0.4% was instilled to anesthetize the surface of the cornea before measurement of IOP. Values of IOP displayed as valid after six rebounds were recorded, and the average was used as the final value.

Histological analysis

Rats were sacrificed by CO_2 inhalation after the final measurement of IOP. Eyes were enucleated and fixed in 10% formalin neutral buffer solution for 2 h. After a sucrose gradient (10%, 20%, 30%), halved eyes were frozen in in optimal cutting temperature (OCT) compound (Tissue-Tek). Cryosections (16 μm) cut with the cryostat were blocked with Blocking One (Nacalai Tesque). Sections were incubated overnight with anti-fibronectin antibody at 4°C. After washing with TBS-T, the sections were incubated with Alexa Fluor 488–conjugated anti-rabbit IgG. After additional washing with TBS-T, samples were mounted with ProLong Gold Antifade Mountant with DAPI (Thermo Fisher Scientific). Images were taken using a BIOREVO BZ-9000 (KEYENCE) and merged into Z-stack images with a BZ-II analyzer (KEYENCE). For quantification of fibronectin, the percentage of the area above the threshold within the trabecular meshwork was calculated using ImageJ Fiji.

Cell adhesion assay

Trabecular meshwork cells were incubated with serum-free DMEM with or without reagents for 48 h. The centrifuged cells were resuspended in serum-free DMEM after detachment with trypsin-EDTA. Cell suspensions (1×10^3 cells/well) were plated on collagen type I–coated 96-well plates and

incubated for 60 min at 37°C. After removal of the medium and washing with D-PBS, the attached cells were quantified by CellTiter-Glo Luminescent Cell Viability Assay (Promega).

Migration assay

Migration was assessed using the CytoSelect 96-Well Cell Migration Assay (Cell Biolabs). Trabecular meshwork cells treated with siRNA were incubated with serum-free DMEM for 24 h. After detachment with trypsin-EDTA, the cells were pelleted by centrifugation and resuspended in serum-free DMEM. Cell suspensions (1×10^4 cells) were applied to the upper chamber, and 3 ng/mL TGF-β2 was added to the lower chamber. Migratory cells were quantified after incubation for 8 h.

Gel contraction assay

The Collagen Gel Culturing Kit (Nitta Gelatin) was used for the collagen gel contraction assay. Trabecular meshwork cells were trypsinized and resuspended in serum-free DMEM at 1×10^6 cells/mL. Cell suspensions were added to a mixture of collagen solution, Solution C, and 10× DMEM on ice (1:7:1:1). The mixture (0.5 mL) was loaded into a 24-well plate coated with 1% BSA, and incubated at 37°C for 1 h. Collagen gels were formed by incubation at 37°C for 90 min, and then 0.5 mL of serum-free DMEM, with or without reagents, was added to the gels. After 1 h incubation, the collagen gels were scraped off the walls of the wells with a spatula. Gel area was measured after incubation for 24 h. Images of gels were taken with a digital camera (EOS M3, Canon), and the area of gels was quantified with a BZ-II analyzer (KEYENCE).

Enzyme-linked immunosorbent assay (ELISA)

Culture supernatants of trabecular meshwork cells were collected and the concentration of tPA or fibronectin in the supernatants was quantified using Duoset ELISA (tPA: DY7449-05, fibronectin: DY1918-05; R&D Systems) or the Quantikine ELISA Kit (DTPA00; R&D Systems).

Statistical analyses

The data are presented as mean ± SEM. Statistical analyses of quantitative data were performed by using the t-test or Dunnett test. A P value of less than 0.05 was considered statistically significant.

Results

Dasatinib, a potent Src family kinase inhibitor, suppressed the elevation of IOP induced by TGF-β2

To evaluate the contribution of SFK activity to IOP elevation induced by TGF-β2, I first performed an *in vivo* experiment in rat eyes. Repeated injection of TGF-β2 into the anterior chamber of rat eyes induced elevation of IOP, which was determined using a TonoLab tonometer. Elevation of IOP by TGF-β2 was significantly suppressed by simultaneous injection of dasatinib, a potent SFK inhibitor (Fig. 5). These results suggest that SFK is involved in the elevation of IOP induced by TGF-β2.

Src is activated by TGF-β2 in trabecular meshwork cells

To verify whether Src is involved in TGF-β-induced IOP elevation, I analyzed the effects of TGF-β2 on tyrosine kinase signaling in human primary trabecular meshwork cells. I first characterized trabecular meshwork cells used in this study by analysis of myocilin expression after treatment of dexamethasone, since the upregulation of myocilin by glucocorticoids is a reliable marker for trabecular meshwork cells. Treatment with dexamethasone dramatically induced expression of myocilin mRNA as reported previously (Nguyen et al., 1998) (Fig. 6A). Next, I investigated the effects of TGF-β2 using these trabecular meshwork cells. TGF-β2 treatment induced morphological changes, with cells converting from a rod-like shape to a more enlarged and spread morphology (Fig. 6B). Upregulation of N-cadherin, an EMT marker, was also observed after TGF-β2 treatment (Fig. 7A and 7B), indicating that these cells were sensitive to TGF-β2. These observations demonstrate that the cells used in this study had the typical features of trabecular meshwork cells.

Immunoblot analysis with anti-phosphotyrosine antibody revealed that the tyrosine phosphorylation levels of 125 kDa, 100 kDa, 68 kDa, and 60 kDa proteins increased after TGF-β2 treatment (Fig. 7A). Analysis with an antibody specific for the active form of Src (pTyr418) showed

that levels of active Src were significantly increased 48 h after TGF-β2 treatment (Fig. 7A and 7C). In addition, immunoprecipitation assays with anti-Src antibody confirmed that Src was indeed activated by TGF-β2 treatment in trabecular meshwork cells (Fig. 8).

Src activity is involved in TGF-β2 signaling

I next investigated the contribution of Src activity to TGF-β2 signaling in trabecular meshwork cells. Immunofluorescence analysis revealed that TGF-β2 treatment induced morphological changes that were accompanied by the accumulation of paxillin, F-actin, and active Src (pY418) at focal adhesions. Treatment with dasatinib suppressed these morphological changes and the assembly of focal adhesions (Fig. 9). Furthermore, immunoblot analysis revealed that TGF-β2–induced tyrosine phosphorylation of cellular proteins including the 100 kDa protein (Fig. 10A), FAK, paxillin, and Src (Fig. 10B and 10C) was abolished by treatment with dasatinib or SD-208, an inhibitor of the TGF-β receptor. These results demonstrate that Src activity is involved in TGF-β2 signaling via the TGF-β receptor.

Src activation is involved in TGF-β2–induced phenotypic changes in trabecular meshwork cells

I showed that TGF-β2 induced accumulation of active Src at focal adhesion sites, suggesting that TGF-β2 facilitates the ECM–cell adhesion via Src activation. To verify this in a quantitative manner, I performed cell adhesion assays on collagen type I. Cell adhesion was significantly promoted by TGF-β2, but inhibited by dasatinib and SD-208 (Fig. 11A). Because IOP is regulated by contraction and relaxation of the trabecular meshwork tissues, I also performed collagen gel contraction assays. TGF-β2 treatment increased the ability of trabecular meshwork cells to contract the collagen gel, and this effect was significantly inhibited by dasatinib (Fig. 11B). These results suggest that Src activity is involved in TGF-β–induced phenotypic changes in trabecular meshwork cells.

To further confirm the role of Src in the regulation of the trabecular meshwork, I induced Src activation by knocking down CSK, a negative regulator of SFKs. CSK knockdown increased

phosphorylation of Src Y418 and FAK Y576 (Fig. 12), and caused paxillin and active Src to accumulate at focal adhesions, as observed in TGF-β2–treated cells (Fig. 13). Furthermore, cell adhesion and migration assays revealed that cell adhesion to collagen type I and cell migration induced by TGF-β2 were significantly promoted by CSK knockdown (Fig. 14). These results indicate that CSK knockdown leading to Src activation phenocopied the changes observed in TGF-β2–treated trabecular meshwork cells.

Expression of tissue plasminogen activator is suppressed by Src activation

To explore IOP-related genes that are regulated by TGF-β2 or Src, I performed microarray analysis of trabecular meshwork cells treated with TGF-β2. Among the genes whose expression levels were significantly altered by TGF-β2, I focused my analysis on genes related to regulation of ECM (Table 2 and Table 4), which potentially play important roles in IOP elevation. To further dissect the contribution of Src activity to gene expression, I examined the effects of dasatinib on the expression of certain genes. Dasatinib did not appreciably influence TGF-β2–dependent upregulation of fibronectin, collagen type 4A1, integrin-β3 or TGF-β2, indicating that expression of these genes is not directly regulated by Src signaling (Fig. 15). By contrast, TGF-β2–dependent downregulation of tissue plasminogen activator (tPA) was inhibited by dasatinib (Fig. 15), suggesting that Src is directly involved in the regulation of tPA expression. Further analysis of tPA expression revealed that dasatinib upregulated tPA production, and TGF-β2-induced downregulation of tPA production was restored by dasatinib (Fig. 16). Likewise, CSK knockdown leading to Src activation decreased tPA production, whereas dasatinib restored tPA production (Fig. 17). These results demonstrate that TGF-β2–induced activation of Src contributes to downregulation of tPA, which plays a crucial role in the regulation of ECM homeostasis (Gerometta et al., 2013; Yang et al., 2005).

Upregulation of CasL leads to functional activation of Src

In trabecular meshwork cells, I observed that TGF-β2 treatment promoted tyrosine phosphorylation of an unknown 100 kDa protein in parallel with phosphorylation of Src substrates, including FAK and paxillin (Fig. 7A, 10A, and 10B). These observations suggest that the 100 kDa protein could be functionally associated with Src signaling. To identify the protein, I performed immunoprecipitation with anti-phosphotyrosine antibody followed by LC-MS/MS analysis. Among several candidates (Table 3), I focused analysis on CasL (also designated as NEDD9 or HEF1), because CasL is an approximately 100 kDa protein that serves as a scaffold protein for Src and FAK (Izumchenko et al., 2009). Immunoprecipitation with anti-CasL antibody verified that the 100 kDa phosphoprotein was indeed CasL (Fig. 18).

Expression of CasL at the mRNA and protein levels was upregulated by TGF-β2 treatment (Fig. 19A). However, mRNA expression was not inhibited by dasatinib, suggesting that CasL upregulation precedes Src activation (Fig. 19B). To characterize the functional interaction between Src and CasL, I introduced Src and/or CasL into HepG2 cells in order to achieve efficient expression of both proteins. Co-immunoprecipitation assays revealed that overexpressed CasL interacted with overexpressed Src (Fig. 20A). Under these conditions, the activity of Src (pY418) was increased (Fig. 20B), suggesting that upregulation of CasL leads to activation of Src via a functional interaction, consistent with a previous report (Sima et al., 2013). To confirm the role of CasL in trabecular meshwork cells, I nucleofected the vector containing the CasL gene and CasL siRNA into trabecular meshwork cells. Overexpression of CasL induced the activation of endogenous Src (Fig. 21A and 21B) and the downregulation of tPA production (Fig. 21C). Conversely, CasL knockdown suppressed TGF-β2–induced upregulation of fibronectin (Fig. 22A and 22B). These results indicate that CasL upregulation leads to functional activation of Src in trabecular meshwork cells.

Src is involved in TGF-β2–induced deposition of extracellular matrix in the trabecular meshwork

I explored the deposition of ECM induced by TGF-β2 in the trabecular meshwork. TGF-β2 induced the accumulation and secretion of fibronectin in trabecular meshwork cells (Fig. 23). To investigate the link between deposition of ECM and increased IOP (Fig. 5), I performed immunofluorescence analysis of rat eyes after repeated injection of TGF-β2 into the anterior chamber. Fibronectin deposition in the trabecular meshwork was increased by TGF-β2, but significantly attenuated by dasatinib (Fig. 24).

Discussion

In this study, I investigated the molecular mechanism responsible for elevation of IOP in glaucoma by analyzing the phenotypic changes induced by TGF-β2 in trabecular meshwork cells. A hypothetical model for TGF-β2–induced IOP elevation in glaucoma is depicted in Fig. 25. In this model, stimulation with TGF-β2 induces upregulation of genes encoding ECM proteins, integrins, and CasL. CasL functions as an activating scaffold of Src, resulting in activation of focal adhesions and actin cytoskeleton. Activation of Src further suppresses the expression of tPA, which contributes to abnormal accumulation of ECM. The auto-upregulation of TGF-β further potentiates these cellular events by forming a positive-feedback circuit. As a consequence, trabecular meshwork tissues are physically remodeled, thus developing resistance to outflow of aqueous humor. The resultant elevation of IOP then leads to the onset of POAG.

My *in vivo* study demonstrated that repeated injection of TGF-β2 increased IOP in rat eyes, consistent with the results of a previous report (Hill et al., 2015), and that dasatinib treatment attenuated the elevation of IOP induced by TGF-β2. I used dasatinib to inhibit Src activity in this study since it was assumed that the phenotype of single SFK knockdown or knockout could not be identified due to functional redundancy among SFKs. Dasatinib is a potent dual inhibitor of Src family kinases with an IC50 in the subnanomolar range and Abl with an IC50 in a few nanomolar range (Lee and Gautschi, 2006; Lombardo et al., 2004). However, Abl is expressed at a negligible level in trabecular meshwork cells (Fig. 26). Dasatinib also inhibits receptor tyrosine kinases such as c-KIT, PDGFRβ, and EPHA2 with an IC50 in a dozen nanomolar range. Given the inhibitory activity, dasatinib is less likely to act on these receptor tyrosine kinases in this study although the possibility cannot be completely denied. Furthermore, PP2, another Src family kinase inhibitor, has been shown to decrease IOP in ocular normotensive rabbits (Kirihara et al., 2014). These suggest that the effect of dasatinib can be largely attributed to inhibition of Src family kinase. Dasatinib is known to inhibit c-Src, Lck,

c-Yes, and Fyn within Src family kinases. Meanwhile, microarray analysis showed that the expression of Lck was negligible, suggesting that dasatinib could inhibit c-Src, c-Yes, and Fyn in the trabecular meshwork (Table 5). Immunoprecipitation assay with anti-Src antibody showed that Src was phosphorylated by TGF-β2. Although I attempted to perform immunoprecipitation assay with anti-Fyn and anti-Yes antibodies in preliminary study, the apparent phosphorylation of Fyn and c-Yes by TGF-β2 treatment was not observed (Fig. 27). Taken together, these results support my conjecture that Src activity is involved in the regulation of IOP. However, it is impossible to completely rule out the possibility that dasatinib affects other kinases. Further investigation is required in order to clearly show that the reduction of IOP by dasatinib is only attribution to Src inhibition.

I used commercially available primary human trabecular meshwork cells in this study. The trabecular meshwork cells were used in several studies including the investigation of the cellular events induced by TGF-β2 (Inoue-Mochita et al., 2015). The trabecular meshwork cells were characterized by immunofluorescence with specific antibodies against α-smooth muscle actin (negative) and fibronectin (positive) according to manufacturer's certificate of analysis. Furthermore, I confirmed that dexamethasone induced drastic upregulation of myocilin mRNA. These indicate that the cells used in this study possessed typical features of trabecular meshwork cells. In future experiments, the results obtained by using trabecular meshwork cells are to be verified in an *in vivo* study.

To determine the molecular mechanisms underlying Src-mediated elevation of IOP, I examined Src function in human trabecular meshwork cells. I observed that TGF-β2 induced functional activation of Src due to phosphorylation of Src Y418 and the accumulation of active Src (pY418) at focal adhesions, resulting in increased levels of actin fibers and focal adhesions in trabecular meshwork cells. Focal adhesions connect ECM and intracellular actin fiber via integrins, and the interaction between ECM and integrin induces formation of protein complexes containing Src, FAK, and paxillin at focal adhesions. Src plays key roles in the regulation of signal transduction from

focal adhesions (Playford and Schaller, 2004), and also promotes cytoskeleton remodeling, cell adhesion, and motility (Carragher and Frame, 2004; Matsuyama et al., 2016). Therefore, Src signaling is induced by the accumulation of active Src at focal adhesions even though Src is not highly phosphorylated. Indeed, TGF-β2–induced cellular events were inhibited by dasatinib, and, conversely, CSK knockdown leading to Src activation phenocopied the effects induced by TGF-β2. These results indicate that functional activation of Src is implicated in TGF-β2–induced cytoskeletal remodeling and focal adhesion formation in trabecular meshwork cells. I also observed that dasatinib inhibited TGF-β2–induced contraction of collagen gel in which the trabecular meshwork cells were embedded. Because contraction of the trabecular meshwork is thought to increase IOP (Nakajima et al., 2005; Wiederholt et al., 2000), it is likely that Src-mediated modulation of cytoskeleton is involved in the elevation of IOP.

Microarray and qRT-PCR analyses revealed that TGF-β2 induced expression of genes related to the focal adhesion complex, including integrin and ECMs. These changes were not inhibited by dasatinib, indicating that these genes are regulated upstream of Src. Thus, expression of components of focal adhesions is directly regulated by TGF-β signaling, but subsequent activation of Src is involved in assemble and activating the focal adhesion complex, enabling it to exert its function. Interestingly, my data showed that TGF-β2 upregulated its own expression, suggesting that a positive-feedback circuit accelerates the functional activation of the trabecular meshwork.

The abnormal deposition of ECM is thought to be one of the main causes of reduced outflow aqueous humor (Lutjen-Drecoll et al., 1989; Vranka et al., 2015). tPA, which degrades ECM by activating plasminogen and matrix metalloproteinase (Haraguchi et al., 2001; Yang et al., 2005), is implicated in the elevation of IOP. tPA is downregulated by glucocorticoids, which is another risk factor for IOP elevation (Kersey and Broadway, 2006; Seftor et al., 1994), and injection of tPA into the anterior chamber or overexpression of tPA decreases IOP in animal models of glucocorticoid-induced ocular hypertension (Gerometta et al., 2013; Kumar et al., 2013). These observations suggest that tPA

plays a key role in ECM regulation in the trabecular meshwork, and that its downregulation is associated with IOP elevation. I found that tPA was downregulated by TGF-β2, as well as by CSK knockdown leading to Src activation, whereas dasatinib treatment restored tPA expression. These observations suggest that downregulation of tPA through Src activation contributes to ECM remodeling, leading to IOP elevation. Moreover, I showed that expression of tPA is regulated by Src at the transcriptional level. tPA expression is increased by inhibition of histone deacetylase (HDAC) in vascular endothelial cells, and HDAC3 is activated by Src (Larsson et al., 2012; Longworth and Laimins, 2006). These results raise the possibility that activated Src decreases expression of tPA via HDAC activation in the trabecular meshwork as well, although further analysis is required to verify this possibility.

I found that a 100 kDa protein was phosphorylated on tyrosine by TGF-β2 treatment; LC-MS/MS analysis and immunoprecipitation assay identified this protein as CasL, an activating scaffold of FAK and Src (Izumchenko et al., 2009). I also observed that CasL expression was upregulated by TGF-β2, whereas dasatinib did not suppress CasL upregulation, indicating that CasL upregulation precedes Src activation. However, dasatinib inhibited phosphorylation of CasL, and overexpressed CasL interacted with and activated Src. These findings suggest that upregulated CasL interacts with Src to activate it, and that activated Src in turn phosphorylates CasL to create binding sites for additional signaling molecules, including Src and FAK. Thus, assembly of the signaling complex, i.e., the focal adhesion, is promoted. A similar interaction between CasL and Src was reported in HaCaT cells (Sima et al., 2013). Together, these findings suggest that a positive-feedback loop exists between Src and CasL in some cell types. Given that CasL is upregulated by TGF-β2 in the trabecular meshwork cells, it may act as a triggering molecule of Src-mediated signaling cascades associated with elevation of IOP in glaucoma. Although I focused my analysis on overexpression of CasL to identify the function as Src activator in trabecular meshwork cells in this study, further experiments are required to clarify the role of endogenous CasL in Src activation induced by TGF-β2.

Repeated injection of TGF-β2 increases IOP due to deposition of ECM in the trabecular meshwork (Hill et al., 2015). I showed that dasatinib treatment attenuated fibronectin deposition induced by TGF-β2 within the trabecular meshwork in rat eyes. The concentration of fibronectin in aqueous humor is higher in glaucoma patients than in controls (Kim et al., 1992), and the level of fibronectin in the trabecular meshwork increases with the pathological stage of glaucoma, as well as with aging (Babizhayev and Brodskaya, 1989). A recent report suggested that fibronectin fibrils were implicated in the assembly of ECM such as collagen IV and laminin by acting as a scaffold (Filla et al., 2017). These findings provide evidence for a functional link between fibronectin deposition and IOP. I found that TGF-β2 upregulated expression of fibronectin mRNA in trabecular meshwork cells, but was not inhibited by dasatinib. Nonetheless, dasatinib and CasL knockdown decreased deposition of fibronectin. This inconsistency could be explained by the upregulation of tPA production induced by dasatinib.

In summary, I demonstrated that the Src signaling pathway is involved in the elevation of IOP induced by TGF-β2, which plays a crucial role in POAG. Activated Src promotes remodeling of the trabecular meshwork via the upregulation of focal adhesions and ECM, and the downregulation of tPA, which is involved in ECM degradation. These Src-mediated cellular events may lead to IOP elevation by increasing resistance to aqueous humor outflow in trabecular meshwork tissues. These findings provide insights into the mechanisms underlying IOP elevation in glaucoma, and suggest that the Src signaling pathway represents a promising target for ocular hypotensive drugs for use against POAG.

Figure 1. Structure of the retina and visual field. (**A**) Retina is composed of ten layers (left panel). The right panel shows the diagram illustrating retinal cells. (**B**) Hematoxylin and eosin-stained retinal histologic sections of rats. (**C**) Visual field simulation of a person with normal vision (left panel) and glaucoma (right panel).

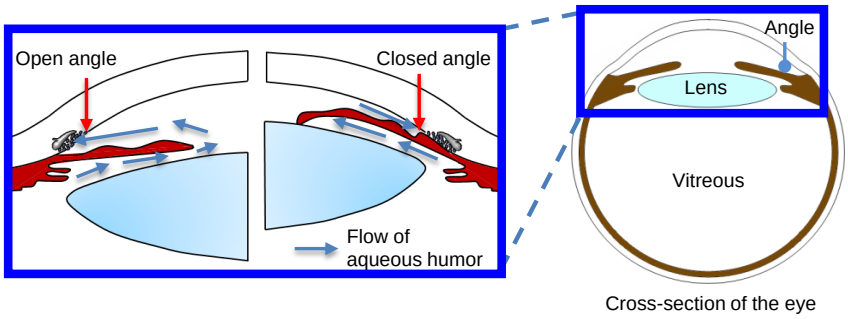

Figure 2. The differences between open-angle glaucoma and angle-closure glaucoma. Glaucoma is classified into open-angle and angle-closure glaucoma. The angle between iris and cornea is open in open-angle glaucoma. In contrast, the angle is usually blocked by iris in angle-closure glaucoma.

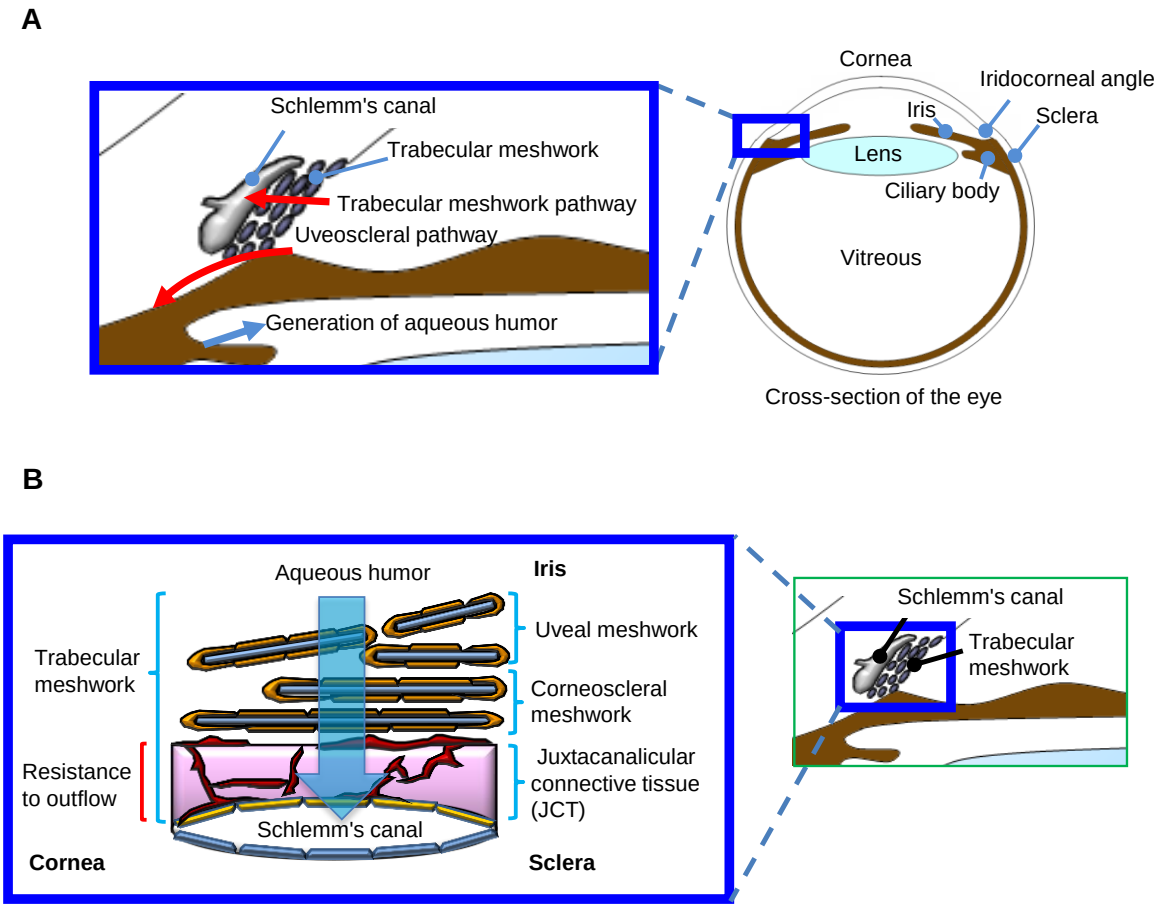

Figure 3. Structure of the eye and aqueous humor dynamics. (**A**) IOP is regulated by the balance between the production by the ciliary body and drainage of aqueous humor via trabecular meshwork and the uveoscleral pathway. In humans, the aqueous humor is drained mainly through the trabecular meshwork. (**B**) Trabecular meshwork consists of three cell layers (uveal meshwork, corneoscleral meshwork, and juxtacanalicular connective tissue). Aqueous humor outflow resistance is generated in inner wall of Schlemm's canal and juxtacanalicular connective tissue (JCT) consisted of cells and ECM.

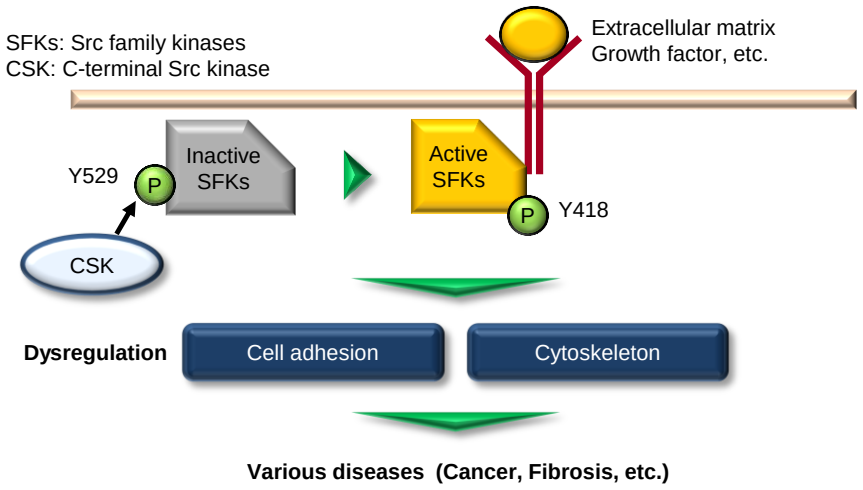

Figure 4. Regulation of Src family kinases. The activity of Src family kinases is strictly regulated by tyrosine phosphorylation at specific sites. In the resting state, Src is phosphorylated at Tyr529 by CSK, causing it to adopt an inactive conformation. In response to stimulation by extracellular signals, such as ECMs and growth factors, Src is activated via autophosphorylation at Tyr418. Dysregulation of SFKs is associated with various diseases, including cancer and fibrosis.

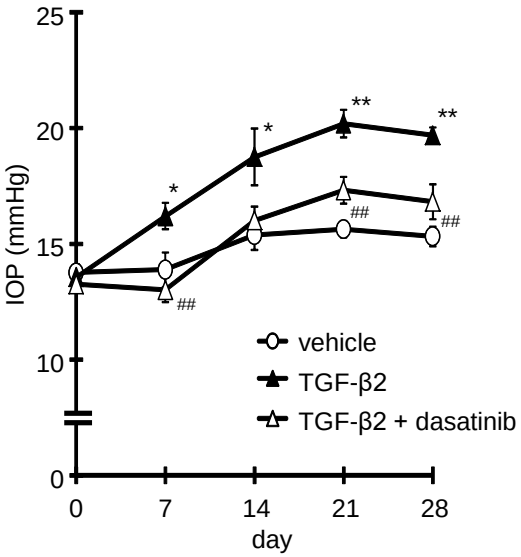

Figure 5. Dasatinib, a potent Src family kinase inhibitor, suppresses IOP elevation induced by TGF-β2. Vehicle and TGF-β2 (5.25 ng/eye) with or without dasatinib (35 pmol/eye) were injected into the anterior chamber of rats twice a week. IOP was measured (mean ± SEM, n = 8) using TonoLab. * $P < 0.05$, ** $P < 0.01$ vs. vehicle (unpaired t-test), ## $P < 0.01$ vs. TGF-β2 (unpaired t-test).

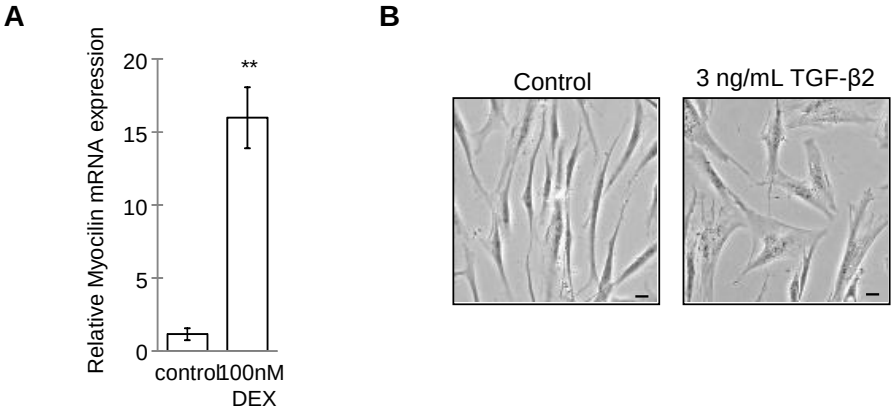

Figure 6. The response of trabecular meshwork cells to dexamethasone and TGF-β2. (**A**) qRT-PCR was performed on cells incubated for 72h with or without 100 nM dexamethasone (DEX) in serum-free DMEM. Data are presented as mean ± SEM (n = 4). ** P < 0.01 vs. control (unpaired t-test). (**B**) Trabecular meshwork cells were treated for 48 h with or without 3 ng/mL TGF-β2 cells in serum-free DMEM. Cell morphology was observed by phase-contrast microscopy (IX71, OLYMPUS) at a magnification of ×200. Scale bar = 20 μm.

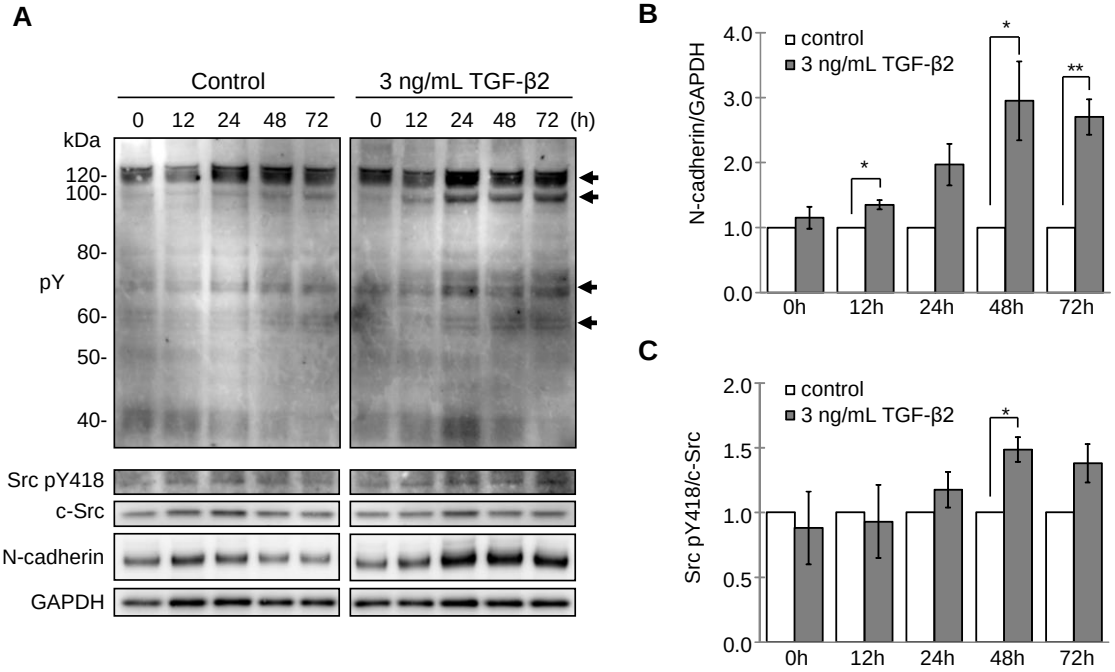

Figure 7. Levels of active Src is increased after TGF-β2 treatment in trabecular meshwork cells. (**A**) Trabecular meshwork cells were treated with 3 ng/mL TGF-β2 in serum-free DMEM. Figure 22. CasL knockdown suppresses TGF-β2–induced upregulation of fibronectin in trabecular meshwork cells. (**A**) Trabecular meshwork cells nucleofected with the indicated siRNAs were incubated for 24 h with DMEM supplemented with 10% FBS, followed by incubation with serum-free DMEM. Total cell lysates were immunoblotted with the indicated antibodies. (upper panels). (**B**) After incubation, culture supernatants were subjected to fibronectin ELISA (mean ± SEM, n = 4). ** P < 0.01 (unpaired t-test), # P < 0.05, ## P < 0.01 (Dunnett test) (lower panel). #1 and #2 indicate CasL siRNA No.1 and No.2, respectively.

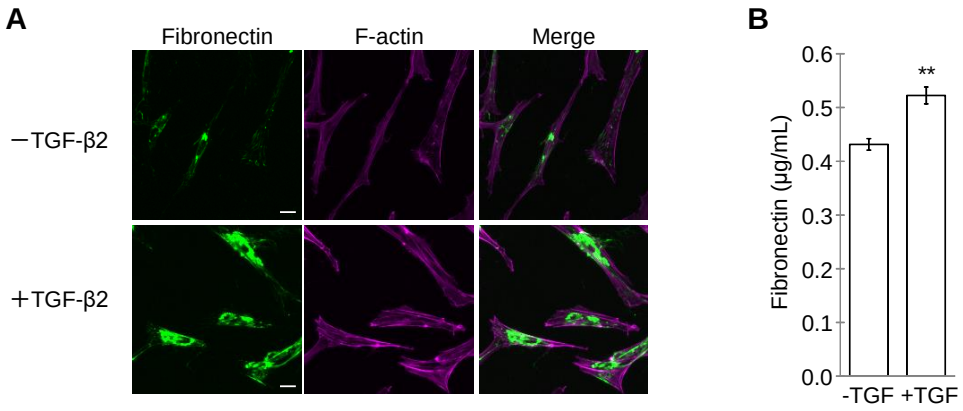

Figure 23. TGF-β2 induces the accumulation and secretion of fibronectin in trabecular meshwork cells. (**A**) Trabecular meshwork cells were incubated with or without 3 ng/mL TGF-β2 in serum-free DMEM for 24 h (fibronectin ELISA) or 48 h (immunostaining). Cells immunostained with anti-fibronectin and phalloidin were observed by fluorescence microscopy (left panels). Scale bar = 20 μm. (**B**) Supernatants after incubation were subjected to fibronectin ELISA (mean ± SEM, n = 8). ** $P < 0.01$ (unpaired t-test).

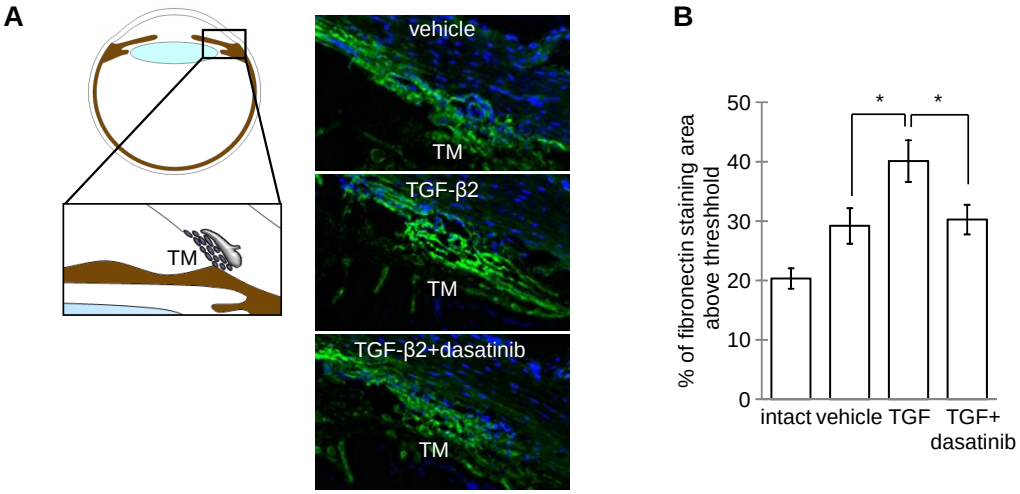

Figure 24. Src is involved in TGF-β2–induced ECM deposition in the trabecular meshwork. (**A**) The diagram illustrates the cross-section of the eye and the magnified view around the trabecular meshwork. TM indicates trabecular meshwork (left panel). After the last measurement of IOP, rat eyes were immunostained with anti-fibronectin (green). Blue immunofluorescent staining indicates nuclear staining with 4',6-diamidino-2-phenylindole (DAPI) (middle panels). Scale bar = 20 μm. (**B**) Fibronectin within trabecular meshwork was quantified (mean ± SEM, n = 7–8). * $P < 0.05$ (unpaired t-test).

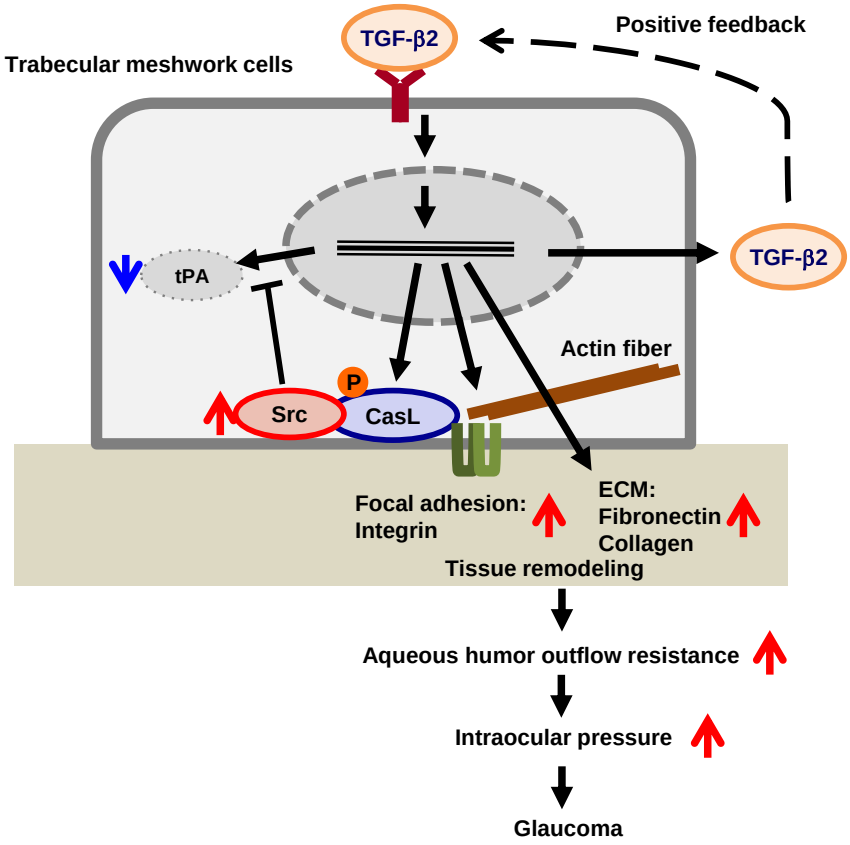

Figure 25. Hypothetical mechanism for TGF-β2-induced IOP elevation in glaucoma. TGF-β2 induces phosphorylation of Src and the upregulation of CasL, actin fiber, integrin, and ECM, resulting in formation of a focal adhesion complex. TGF-β2 is also upregulated through positive feedback. Upregulated CasL activates Src, which in turn downregulates tPA, which is involved in ECM degradation. These changes affect tissue remodeling, resulting in elevation of IOP by increasing resistance to aqueous humor outflow in the trabecular meshwork.

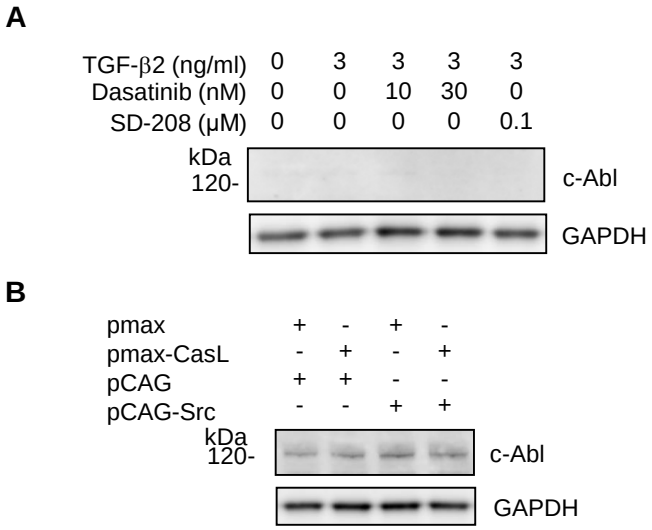

Figure 26. Expression of c-Abl in trabecular meshwork cells and HepG2 cells. (**A**) Trabecular meshwork cells were incubated with serum-free DMEM containing the indicated reagents for 48 h. Lysates were subjected to immunoblotting with the indicated antibodies. (**B**) HepG2 cells were transfected for 24 h with the indicated constructs in DMEM supplemented with 10% FBS. After incubation with serum-free DMEM for 24 h, total cell lysates were prepared and immunoblotted with the indicated antibodies.

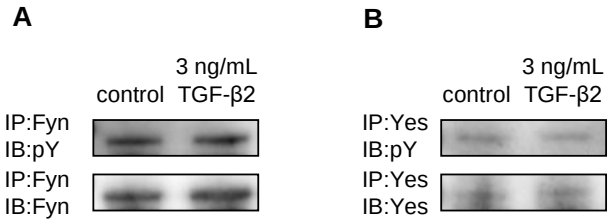

Figure 27. Effects of TGF-β2 on the phosphorylation of Fyn and Yes. (**A**) Anti-Fyn and (**B**) Anti-Yes immunoprecipitates from cells treated with or without 3 ng/mL TGF-β2 for 48 h in serum-free DMEM were subjected to immunoblotting with the indicated antibodies.

Tables

Table 1. Primer sequences for qRT-PCR

	Sequence	
Name	**Forward**	**Reverse**
GAPDH	GCAGGGGGGAGCCAAAAGGGT	TGGGTGGCAGTGATGGCATGG
tPA	TGTGCTGGAGACACTCGG	ACGAATCCAGTCTAGGTAGTTGG
CasL	GATGACTACGATTACGTCCACCTAC	CTCTGAGAGGGCTTCCACTTC
fibronectin1	CTGAACTGTACATGCTTCGGT	AGATGGCTGTGGTGCATTC
COL4A1	AGGCACAGGACCTTTGGGA	GGGAGCCCATCTCTTCCACTT
Integrin β3	TGCCCCAGAATCCATCGAGT	GGTTACTGGTGAGCTTTCGCA
TGF-β2	CAAGAGCAGAAGGCGAATGG	TCACCACTGGTATATGTGGAGG
Myocilin	AGCAAGGCTGAGAAGGGG	GGCTCTCCTTCAAAATTCGGG

Table 2. Representative ECM-related genes regulated by TGF-β2

Protein name of down-regulated gene	**Fold change**	
	24 h	**48 h**
Plasminogen activator, tissue	0.39	0.82
ADAM metallopeptidase with thrombospondin type 1 motif, 9	0.07	0.16
ADAM metallopeptidase with thrombospondin type 1 motif, 14	0.26	0.16
ADAM metallopeptidase with thrombospondin type 1 motif, 19	0.62	0.49

Protein name of up-regulated gene	**Fold change**	
	24 h	**48 h**
Fibronectin 1	1.74	2.34
Elastin	5.02	4.27
Laminin, gamma 1	2.03	1.56
Laminin, gamma 2	6.82	10.27
Laminin, gamma 3	2.08	1.08
Collagen, type I, alpha 1	5.10	4.41
Collagen, type IV, alpha 2	4.00	3.54
Collagen, type VIII, alpha 2	13.09	13.45
Integrin, alpha V	2.53	2.16
Integrin, alpha 1	1.39	0.97
Integrin, beta 3	2.11	2.99
Transforming growth factor, beta 1	2.38	2.11
Transforming growth factor, beta 2	2.23	1.67

Data are presented as averages.

Table 3. List of representative proteins identified by LC-MS/MS analysis

Identified proteins	Molecular weight (kDa)	Probability			
		sample1	sample2	sample3	sample4
Focal adhesion kinase 1	119	64.61	51.31	82.37	54.6
Enhancer of filamentation 1 (CasL, NEDD9)	93	28.19	25.96	50.43	37.89
Programmed cell death 6-interacting protein	96	27.02	22.94	33.62	36.77
Breast cancer anti-estrogen resistance protein	93	14.1	19.92	18.49	24.52
Bone morphogenetic protein receptor type-2	115	9.4	13.88	15.13	15.6
Phosphatidylinositol 4,5-bisphosphate 3-kinase catalytic subunit alpha isoform	124	5.87	16.3	1.68	7.8
Ephrin type-B receptor 4	108	15.27	13.28	10.09	12.26
ATP-citrate synthase	121	14.1	13.28	8.4	11.14
Ras GTPase-activating protein 1	116	10.57	10.87	13.45	14.49
NEDD4-like E3 ubiquitin-protein ligase WWP2	99	10.57	11.47	11.77	11.14

Table 4. List of ECM-related genes regulated by TGF-β2

			3ng/mL TGF-β2

Table 5. Expression of Src family kinases in microarray analysis

Src family kinases	Molecular weight	Signal Evaluation	
		control	TGF-β2
Lyn	56 kDa	2	2
Lck	56 kDa	1	1
Hck	59 and 61 kDa	0	1
Fyn	59 kDa	2	2
c-Fgr	56 kDa	2	2
Blk	55 kDa	0	0
c-Yes	60 kDa	2	2
c-Src	60 kDa	2	2

Signal evaluation: 0; transcripts were not detected, 1; signals for transcripts were insufficient, 2; transcripts were detected.

Src mediates TGF-β–induced intraocular pressure elevation in glaucoma
Journal of Cellular Physiology, in press, 2018

Acknowledgments

I would like to express my deepest gratitude to Prof. Masato Okada for his great support, advice, discussion, and encouragement. I am especially grateful to Dr. Shigeyuki Nada and Dr. Kentaro Kajiwara for their helpful advices.

I would like to thank the Core Instrumentation Facility, Research Institute for Microbial Diseases, Osaka University, for technical assistance with LC-MS/MS analysis.

I would like to express my thanks to Prof. Takahisa Furukawa (Osaka University) and Prof. Hiroaki Miki (Osaka University) for reviewing my thesis.

Finally, I am deeply grateful to my family and all members of Department of Research for their encouragement.

This work was supported by JSPS KAKENHI Grant Numbers 15H04296, 26640078, 26114006, 17H06004, and 17K19596.
