Osaka University
Diffusion Welding of Mild Steel to Aluminium

Nobuya IWAMOTO*, Mitsuhiko YOSHIDA**, Sanetoshi TABATA***, Toshiaki TAKEUCHI***
and Mitsuo MAKINO**

Abstract

Diffusion welding between mild steel and aluminum was carried out under various experimental conditions. Intermetallic layer and the position where fracture occurred were analyzed in each specimen. When nickel interlayer was used in vacuum, the tensile strength of the joint became larger than that of aluminum itself. In other cases, insufficient strengths were obtained.

1. Introduction

Diffusion welding has a benefit that the extent of diffusion of the elements in the weld can be controlled because base metals remain solid state in the process. Therefore, it is thought as a suitable technique to weld metallurgically incompatible dissimilar metals. As for joining between mild steel and aluminum, the following factors, the formation of brittle intermetallic compounds of iron-aluminum and the existence of tenacious oxide film on aluminum, should be kept in mind. Thus, silver or nickel in the form of foil or electroplate was generally used as interlayer to overcome the problems above described 1), 2).

In this report, specimens, welded in inert gas or in vacuum were prepared because treatment in inert gas is important from the industrial viewpoint. The joint was examined with various methods such as tensile test, metallographic observation, X-ray analysis, electron probe microanalysis and ion probe microanalysis.

2. Experimental procedures

2.1 Specimens

SGD2 mild steel and 1050 commercial pure aluminum were used. Their chemical compositions are given in Table 1. After machined to 19 mm x 50 mm, the surface of the specimens were ground by emery papers and buff-polished with 0.3 μm alumina powder. Then, the specimens were degreased by acetone in a few minutes.

The purity of silver foil used as interlayer was 99.98 %, Silver-beryllium alloy containing 0.5% beryllium was also used as interlayer. The electroplating conditions are given in Table 2.

2.2 Welding processes

As shown in Fig. 1, apparatus with resistor type heater was used for diffusion welding in inert gas. Argon gas was flowed into alumina tube at the rate of 5 ml/sec.

On the other hand, experiment in vacuum was carried out with high frequency induction heater. After setting the samples between anvils in a vacuum chamber, it was evacuated to $10^{-5}$ torr vacuum.

The temperature of the joint was measured with the CA thermocouple. The welding conditions are given in Table 3. The specimens were cooled down to 150°C in the apparatus after welding.

### 2.3 Analysis

The microstructure of the joint was observed with an optical microscope. Mechanical strength of the joint was measured and the fracture surface was investigated with ion probe microanalyzer (IMA: Hitachi, type IMA-SS). The experimental conditions of IMA are as follows:

- Primary ion beam diameter: 1 µm
- Ion source: Ar⁺
- Accelerating voltage: 10 kV
- Sample current 2 µA.

Some joints were studied with electron probe microanalyzer (EPMA: Shimadzu, type EMX-SM). X-ray diffraction analysis was made to determine the formation of intermetallic compounds (Rigaku, type D-3F).

### 3. Experimental results

#### 3.1 Diffusion welding without interlayer

When interlayer was not used, the joint strengths were very poor in every case. The intermetallic layer formed in the weld was indentified to be Fe₂Al₅ by X-ray and the fracture occurred at the interface between Fe₂Al₅ and aluminium. To know the distribution of trace elements on the fracture surfaces welded in argon gas, IMA technique was applied. Fig. 2 shows the ratios of the output intensities of various secondary ions to A⁺. Light elements such as carbon, phosphorus and sulphur were enriched on the fracture surface and iron was also detected. It is thought that these elements diffused from mild steel to aluminium and concentrated on the fracture surface. Furthermore, the enrichments of oxygen, titanium and copper were observed. However, relationship between the enrichments of these elements on the fracture surface and the insufficient strength of the joint remains unclear.

Fig. 2. Relative intensities of various elements on fracture surface vs. sputtering time

#### 3.2 Silver interlayer

When silver interlayer was used, the tensile strength of the joint welded in argon gas ranged from 1.0 kg/mm² to 1.6 kg/mm². On the other hand, the tensile strength of the joint welded in vacuum ranged from 1.9 kg/mm² to 2.7 kg/mm². The microstructure of the joint welded in argon gas is shown in Photo. 1. The results by EPMA are shown in Fig. 3 and X-ray diffraction patterns are shown in Fig. 4. The results obtained were as follows:

1. Fe₂Al₅ of about 25 µm thickness was observed in mild steel side.
2. The intermetallic layer of aluminium side was composed of the mixture of Al₈2Al and FeAl₃.
3. The fracture occurred at Fe₂Al₅ layer.

It is known that beryllium has a controlling effect on the growth of iron-aluminium alloy layers. As a trial, silver-beryllium alloy containing 0.5 % beryllium was used as interlayer. Although the addition
of beryllium reduced the thickness of Fe₂₅Al₅ layer to 15 μm, the joint strength was not improved.

3.3 Nickel interlayer

Nickel was electroplated on mild steel surface as interlayer before welding. The microstructure of the joint welded in argon gas is shown in Photo. 2. X-ray diffraction patterns of the fracture surface of aluminium side are shown in Fig. 5. The joint, welded in vacuum, showed the tensile strength larger than that of aluminium. But the tensile strength of the joint ranged from 1.4 kg/mm² to 2.0 kg/mm² when welding was carried out in argon gas. The intermetallic layers in the weld were consisted of the following compounds in each joint.

1) Al₃Ni₂ of 18 μm thickness and Al₃Ni of 7 μm thickness in the joint welded in argon gas.
2) Al₃Ni₂ of 9 μm thickness and Al₃Ni of 2.5 μm thickness in the joint welded in vacuum.

The fracture of the joint welded in argon gas occurred in Al₃Ni₂ layer, partly in Al₃Ni layer and in the interface between Al₃Ni layer and aluminium. Although it was reported that the thickness of Al₃Ni₂ layer affects on the
strength of the joint\textsuperscript{2)}, it was difficult to control the thickness of Al\textsubscript{3}Ni\textsubscript{2} layer in argon gas.

3.4 Multi-interlayers

As above mentioned, insufficient strength of the joint welded in argon gas could be obtained when a single interlayer was used. As a trial, multi-interlayers consisting of nickel-silver-copper system were used. Nickel of 6 \(\mu\)m thickness was electroplated on mild steel surface. Likewise, copper of 3 \(\mu\)m thickness was electroplated on aluminium surface. Then, these specimens were welded through silver foil of 0.2 mm thickness in argon gas. In comparison with other cases, the joint strength increased to the value ranged from 3.5 kg/mm\textsuperscript{2} to 4.9 kg/mm\textsuperscript{2}. As an example, the microstructure of the joint is shown in Photo. 3.

\includegraphics[width=0.5\textwidth]{photo3.png}
\caption{Microstructure of the joint welded with Ni-Ag-Cu interlayers}
\end{figure}

4. Summary

Mild steel was diffusion welded to aluminium under various experimental conditions. The conclusions obtained are as follows:

1. Without interlayer: Fe\textsubscript{2}Al\textsubscript{5} was formed as intermetallic compound.
2. With silver interlayer: Fe\textsubscript{2}Al\textsubscript{5} was formed in mild steel side.
3. With nickel interlayer: Al\textsubscript{3}Ni\textsubscript{2} and Al\textsubscript{3}Ni were formed in aluminium side.
4. The joint strength was insufficient except when nickel interlayer was used in vacuum.
5. In order to obtain good joint in argon gas, it seems necessary to use multi-interlayer.
