0. In [4] Serre defines an unramified revetement as an affine morphism $\varphi$ of varieties satisfying some particular conditions (see §1) and he shows that every unramified revetement can be obtained as a quotient of a Galois revetement by the action of a subgroup of the Galois group.

Trying to extend these results to arbitrary preschemas we can translate everything to a pure algebraic setting.

In §1 we prove that the conditions for unramified revetement are equivalent to the separability of the associated rings for each affine open set. In §2 we give some complements to Galois theory (as developed in [2] and [6]) and in §3 we prove that every separable algebra can be functorially embedded in a Galois extension.

The results of §2 are either obvious consequences of [6] or they belong to a forthcoming paper by the same authors.

The results of §3 generalize similar results by Auslander and Goldman ([1], Th. A. 7).

1.

Let $\varphi: Y \rightarrow X$ be a morphism of preschemas. If $\theta_Y, \theta_X$ are the structure sheaves of $Y, X$ respectively, then $\varphi_*(\theta_Y)$ is a sheaf $\mathfrak{A}$ of $\theta_X$-algebras.

According to Serre [4] we will say that $\varphi$ is an unramified revetement if

1) $\varphi$ is an affine morphism.
2) $\mathfrak{A}$ is a projective finite $\theta_X$-module.
3) For each $P \subseteq X$, $\text{rad } \mathfrak{A}_P = \mathfrak{A}_P$. $\text{rad } (\theta_X)_P$.
4) $\mathfrak{A}_P / \text{rad } \mathfrak{A}_P$ is separable over $(\theta_X)_P / \text{rad } (\theta_X)_P$.

If $U$ is an affine open set in $X$, $\varphi^{-1}(U)$ is affine in $Y$ by 1). We want to prove that, if $R$ is the ring of $U$ (i.e., $\{U, \theta_X|U\}$ is isomorphic to $\text{Spec } R$ and the associated canonical sheaf) and $S$ is the ring of $\varphi^{-1}(U)$, the previous conditions are equivalent to $S$ being a separable projective $R$-algebra.

This gives the translation from the geometric to an algebraic problem. We will not come back to Geometry, and we will leave as an exercise to the willing
reader to retranslate the results back.

Notation. If \( \nu \) is a prime ideal in \( R \) we shall call \( R_\nu \) the localizations of \( R \) at \( \nu \); for every \( R \)-module \( M \) (resp. \( R \)-algebra \( A \)) call \( M_\nu = M \otimes_R R_\nu \) (resp. \( A_\nu = A \otimes_R R_\nu \)).

**Lemma 1.** Let \( I \) be an ideal in a commutative ring \( R \). Then \( I \subseteq \text{rad } R \) if for every f.g. \( R \)-module \( N \), \( IN = N \Rightarrow N = 0 \).

Proof. If \( I \subseteq \text{rad } R \), let \( N \) be a f.g. module with \( IN = N \), then \( N = 0 \) by Nakayama’s lemma. If \( I \not\subseteq \text{rad } R \), there is a maximal ideal \( \nu \subseteq R \) with \( I + \nu \) = \( R \), hence \( R/\nu = 0 \) and \( I \cdot R/\nu = R/\nu \).

**Lemma 2.** Let \( S \) be a finite commutative \( R \)-algebra. Then \( S \cdot \text{rad } R \subseteq \text{rad } S \).

Proof. If \( N \) is f.g. \( S \)-module, then it is a f.g. \( R \)-module. Since
\[
(S \cdot \text{rad } R) N = \text{rad } R \cdot N,
\]
then
\[
(S \cdot \text{rad } R) N = N \Rightarrow \text{rad } R \cdot N = N \Rightarrow N = 0 .
\]
so by lemma 1:
\[
S \cdot \text{rad } R \subseteq \text{rad } S .
\]

**Corollary.** If \( S \) is a finite \( R \)-algebra with \( R \) local, then \( S \) is semilocal.

**Lemma 3.** Let \( A \) be a ring (not necessarily commutative), \( R \) a subring con-
tained in the center of \( A \) (with the same unit) and \( M \) a finitely generated finitely
presented \( A \)-module. Then, if \( M_\nu \) is \( A_\nu \)-projective for every \( \nu \subseteq R \), then \( M \) is
\( A \)-projective.

Proof. Since \( M \) is assumed finitely presented, then \( M \) is projective if it is flat.

From the canonical isomorphism
\[
[\text{Tor}_A^d(M, N)] \otimes_R R_\nu = \text{Tor}_A^d(M, N)
\]
and the fact that \( M_\nu \) is \( A_\nu \)-flat, we get \( (\text{Tor}_A^d(M, N)) \otimes_R R_\nu = 0 \) for every maximal ideal \( \nu \) of \( R \). Hence \( \text{Tor}_A^d(M, N) = 0 \) for all \( N \) and \( M \) is \( A \)-flat.

**Corollary.** Let \( A \) be an \( R \)-algebra of finite type (\( R \) a commutative ring).
If for every maximal ideal \( \nu \) of \( R \), \( A_\nu \) is separable over \( R_\nu \), then \( A \) is separable
over \( R \).

Proof. \( A \) separable over \( R \) means \( A \) is a projective \( A \otimes_R A^e \)-module. \( R \) is
contained in the center of \( A \otimes_R A^e \) and \( A_\nu \otimes_{R_\nu} A^e_\nu = (A \otimes_R A)_\nu \). On the other
hand, \( A \) of finite type implies \( A \) has finite \( A \otimes A^e \)-presentation. Then lemma 3 applies.

**Lemma 4.** Let \( S \) be a commutative finite \( R \)-algebra with \( R \) local. If for every maximal ideal \( \nu \) of \( S \), \( S_\nu \) is separable over \( R \), then \( S \) is separable over \( R \).

Proof. Consider the inclusion \( \varepsilon_i : S \rightarrow S \otimes_R S \) given by \( \varepsilon_i(x) = x \otimes 1 \). By hypothesis \( S_\nu \) is \( S_\nu \otimes S_\nu \)-projective. Since \( S_\nu \otimes S_\nu \) is \( S_\nu \otimes S_\nu \)-flat, by a change of rings argument we get \( S_\nu \) is \( S_\nu \otimes S_\nu \)-flat. Since \( \varepsilon_i(S) \) is a subring with the same unit in \( S \otimes S \), lemma 3 gives the desired result.

**Theorem 1.** Let \( S \) be a commutative finite \( R \)-algebra. Then \( S \) is separable over \( R \) if and only if for every maximal ideal \( \nu \) of \( R \) the following conditions hold:

1. \( \text{rad} \, S_\nu = S_\nu \cdot \text{rad} \, R_\nu \)
2. \( S_\nu /\text{rad} \, S_\nu \) is separable over \( R_\nu /\text{rad} \, R_\nu \).

The necessity of the conditions is an obvious consequence of the fact that \( S \) separable over \( R \) implies \( S_\nu /\text{rad} \, S_\nu \) is separable over \( R_\nu /\text{rad} \, R_\nu \).

Let us prove the sufficiency:

1. Because of the corollary of lemma 3, it is enough to prove that \( S_\nu \) is separable over \( R_\nu \) for each \( \nu \), hence we may assume \( R \) is local (so \( R = R_\nu \)).

Then \( S \) is semilocal. If for every maximal ideal \( \alpha \) of \( S \), \( S_\alpha \) is separable, then \( S \) is separable over \( R \) (lemma 4).

So we may assume \( S \) is local, \( \text{rad} \, S = S \cdot \text{rad} \, R \) and \( S /\text{rad} \, S \) is a separable field extension of \( R /\text{rad} \, R \), hence there is an element \( \overline{c} \in S /\text{rad} \, S \) such that \( \{1, \overline{c}, \cdots, \overline{c}^{n-1}\} \) is a basis of \( S /\text{rad} \, S \) (as a vector space) over \( R /\text{rad} \, R \).

If \( c \in S \) maps onto \( \overline{c} \), then \( \{1, c, \cdots, c^{n-1}\} \) is a set of generators of \( S \) as an \( R \)-module (by using Nakayama’s lemma). Hence \( c^n \) is a linear combination of \( 1, c, \cdots, c^{n-1} \) so

\[
   c^n + a_{n-1} c^{n-1} + \cdots + a_0 = 0
\]

By reducing modulo the radical, we get

\[
   \overline{c}^n + \overline{a}_{n-1} \overline{c}^{n-1} + \cdots + \overline{a}_0 = 0
\]

and, by counting dimensions, we see this is the minimal equation (hence irreducible and separable) of \( \overline{c} \) over \( R /\text{rad} \, R \). We will call \( \overline{F} \) the image of \( F \in S [x] \) in \((S /\text{rad} \, S) [x] \). Since \( \frac{dF}{dx}(c) = \frac{d\overline{F}}{d\overline{x}}(\overline{c}) \) then \( \frac{d\overline{F}}{d\overline{x}}(\overline{c}) \neq 0 \) implies that the derivative \( \sum_{i=1}^n i a_i \overline{c}^{i-1} \) is invertible in \( S \).
Let \( \mu: S \otimes S \to S \) be the map defined by \( \mu(x \otimes y) = xy \).

To prove that \( S \) is separable over \( R \) we will give an explicit form for the idempotent \( e \in S \otimes S \) such that \( \mu(e) = 1 \) and \((1 \otimes c - c \otimes 1)e = 0\) (this last condition implies \( \text{Ker } \mu \cdot e = 0 \)) since \( \text{Ker } \mu = 0 \) is, in this case, the ideal generated by \( 1 \otimes c - c \otimes 1 \).

We had \( X^n + a_{n-1}X^{n-1} + \cdots + a_0 = F(X) \in R[X] \) with a root \( c \in S \); hence, in \( S[X] \) we have \( F(X) = (X - c)G(X) \). If we call \( F'(X) \) the formal derivative, then \( F'(X) = (X - c)G'(X) + G(X) \), so \( F'(c) = G(c) \) is invertible in \( S \).

Define the maps \( \varepsilon_0, \varepsilon_1 : S \to S \otimes S \) by \( \varepsilon_0(a) = 1 \otimes a \), \( \varepsilon_1(a) = a \otimes 1 \) and call \( \varepsilon_0, \varepsilon_1 \) also the induced maps \( S[X] \to (S \otimes S)[X] \). Now, both \( \varepsilon_0(c) \) and \( \varepsilon_1(c) \) are roots of \( F(X) \) (\( F \) had coefficients in \( R \), hence \( \text{SQF}^S \)).

Define the maps \( \varepsilon_0, \varepsilon_1 : S \to S \otimes S \) by \( \varepsilon_0(a) = 1 \otimes a \), \( \varepsilon_1(a) = a \otimes 1 \) and call \( \varepsilon_0, \varepsilon_1 \) also the induced maps \( S[X] \to (S \otimes S)[X] \). Now, both \( \varepsilon_0(c) \) and \( \varepsilon_1(c) \) are roots of \( F(X) \) (\( F \) had coefficients in \( R \), hence \( \varepsilon_0F = \varepsilon_1F \)), and applying \( \varepsilon_0 \) to

\[
F(X) = (X - c)G(X)
\]

we get

\[
F(X) = (X - \varepsilon_0c) \cdot (\varepsilon_0G(X))
\]

and

\[
F(\varepsilon_1c) = (\varepsilon_1c - \varepsilon_0c)\varepsilon_0G(\varepsilon_1c) = 0.
\]

Since \( G(c) \) is invertible in \( S \), so is \( \varepsilon_0(G(C)) = \varepsilon_0G(\varepsilon_0) \) in \( S \otimes S \). Take \( e = \varepsilon_0G(\varepsilon_0) \), hence, using the fact that \( \mu e = \text{id.} \), \( \mu(e) = 1 \) and \((c \otimes 1 - 1 \otimes c)e = (\varepsilon_0c - \varepsilon_0\varepsilon_0) = 0 \).

2. **Galois extensions**

**Notation.** If \( V \) is separable over \( R \) the unique idempotent \( e \) such that \( 1 - e \) generates \( \text{Ker } \mu: V \otimes_R V \to V \) will be called \( e \) \((V/R)\).

**Definition.** Let \( T \) be a commutative ring with \( 1 \), \( R \) a subring (with the same unit). Then \( T \) is called a *Galois extension of \( R \) with Galois group \( G \) if \( G \) is a finite group of automorphisms of \( T \) such that \( R = T^G \) (i.e. \( R \) is the set of elements of \( T \) invariant under every \( \sigma \in G \)) and \( T \) is projective and separable over \( R \).

It follows that \( T \) is finite over \( R \) ([3], [6]).

Since we assume \( T \) is separable over \( R \), then \( \text{Ker } \mu: T \otimes_R T \to T \) is generated by an idempotent \( 1 - e \). Call \( e_T = (1 \otimes \sigma)(e) \) and \( f_T = \mu(e_T) \).

**Lemma 5.** Let \( T \) be Galois over \( R \). Then \( f_1 = 1 \) and \( f_\sigma \) is an idempotent of \( T \) such that \( \sigma \neq 1 \Rightarrow f_\sigma \neq 1 \).

For every \( x \in S \), \((1 \otimes 1)x = (x \otimes 1)1 \) and applying \( 1 \otimes \sigma \) we obtain \((1 \otimes \sigma(x))e_\sigma = (x \otimes 1)e_\sigma \), hence (applying \( \mu \))

\[
\sigma(x)f_\sigma = x \cdot f_\sigma,
\]

hence, \( f_\sigma \neq 1 \) implies \( x=\sigma(x) \), \( Vx \), so \( \sigma = 1 \). Since \( e' = e \), \((1 \otimes \sigma)e' = e_\sigma^2 = (1 \otimes \sigma)e \neq e_\sigma \), and \( \mu \) is a ring homomorphism \( f_\sigma^2 = f_\sigma \).
Corollary. If $T$ is Galois over $R$ and $T$ has no idempotents, other than 0 and 1, then $f_{\sigma} = \delta_{\sigma}$ (Kronecker $\delta$). In this case, $T$ is Galois in the sense of [2], which we will call C-H-R-Galois.

Corollary. If $T$ is Galois over $R$ with Galois group $G$ and $T$ has no idempotents other than 0 and 1, then $[G:1] = [T:R]$.

Since ([1], Th. 1.3) $T \otimes_R T$ is $T$-isomorphic to a direct sum of as many copies of $T$ as the order of $G$, $T$ being faithfully flat over $R$ implies the corollary.

Since $T$ is finite over $R$, a simple rank argument shows that $T$ has only a finite number of idempotents. Let $m_1, ..., m_k$ be the minimal idempotents of $T$. If we consider $\Sigma m_j$ for all $j$ such that there is a $\sigma \in G$ with $\sigma(Tm_i) = Tm_j$, then $\Sigma m_j$ is an idempotent in $R$, hence $\Sigma m_j = 1$; so, all $Tm_j$ are mutually isomorphic and $G$ acts transitively in the set $\{m_1, ..., m_k\}$. Call $U = Tm_i$.

Then $r = [T:R] = k \cdot [U:R]$

Call $n = [G:1]$

Since $G$ is transitive over $\{m_1, ..., m_k\}$, choose $\sigma_i = \text{id}$, $\sigma_2, ..., \sigma_k$ such that $\sigma_i(m_i) = m_i$.

If we call $G_i = \{\sigma \in G; \sigma(m_i) = m_i\}$ then every element of $G$ can be uniquely written as $\tau \sigma_i(\tau \in G_i)$ for some $i$ (in fact, if $\alpha(m_i) = m_i$, then $\sigma_i^{-1} \alpha \in G_i$). Then

Call $G' = G_i \upharpoonright U$, hence there is an epimorphism $\Phi: G_i \to G'$ and $[G':1] \leq n/k$ (= only if $\Phi$ is an isomorphism). Writing $T = Tm_1 \oplus \cdots \oplus Tm_k$ and identifying $Tm_i$ with $Tm_i$ through $\sigma_i$, any $t \in T$ can be written $t = (a_1, \ldots, a_k)$, $a_i \in U$.

Then $t \in T^G \subseteq R$ if $a_i = a_i$ and $\tau(a_i) = a_i \forall \tau \in G_i$,

hence $U^{G'} = R$.

Since $U$ has no idempotents, then $[G':1] = [U:R]$, $[G':1] = r/k$ hence $r/k \leq n/k$ and $r \leq n$.

Lemma 7. Let $T$ be Galois over $R$ with Galois group $G$. Assume $R$ has no idempotents other than 0 and 1. If $[G:1] = [T:R]$ then $f_{\sigma} = 0$ for every $\sigma \neq 1$.

According to the proof of the previous lemma, $n \Rightarrow r$ if and only if $\Phi: G_i \to G'$ is an isomorphism. If we call $G_i$ the set of $\sigma \in G$ such that $\sigma(m_i) = m_i$, then $\sigma_i$ (the one we chose in that proof) gives an isomorphism $G_i \to G_i$. $\Phi$ being an isomorphism implies (now for every $i$) that from $\sigma(m_i) = m_i$, $\sigma \neq \text{id}$ follows $\sigma \mid Tm_i \neq \text{id}$.
Since $U$ is separable over $R$, let $e(U|R) = \sum x_jy_j$, then $e(S|R) = \sum x_j\sigma(x_j)m_j \otimes \sigma(y_j)m_j$ and $f_\sigma = \sum x_j\sigma(x_j)m_j \otimes \sigma(y_j)\sigma(m_j)$, hence, if $\sigma(m_j) = m_j$ the $m_j$'s being minimal i.p., then $m_\sigma(\sigma(m_j)) = 0$, so, the only remaining terms are those in which $m_j = \sigma(m_j)$. But $\sigma \mp 1$ implies $\sigma | Tm_j | 1$ because $\Phi$ is an isomorphism, hence $\sum_j x_j\sigma(y_j) = 0$ and we are done.

**Theorem 2.** Let $T$ be Galois over $R$ with group $G$. If $T$ has a rank over $R$ and $[G:1] = [T:R]$, then $f_\sigma = 0$ for all $\sigma$ in $G$.

If $(f_\sigma)_\nu = 0$ for every $T_\nu = T \otimes R_\nu$ when $\nu$ runs over all maximal ideals in $R$, then $f_\sigma = 0$. But $R_\nu$ being a local ring, has no i.p. other than 0 and 1. Separability, projectivity and rank are preserved under localization, and $G$ induces $G_\nu$ as $R_\nu$-autos of $T_\nu$ in the obvious way. We have to show that $T_\nu \sigma_\nu = R_\nu$ and $[G_\nu:1] = [T_\nu:R_\nu] = [T:R]$ and then apply the previous lemma. Obviously $R_\nu \subseteq T_\nu \sigma_\nu$.

Let $x \in T_\nu \sigma_\nu$, then $x = y/r \in T_\nu$, $r \in R_\nu$, and $\sigma(x) = \sigma(y)/r$, hence $\sigma(x) = x$ implies the existence of $k \in R$, $k \in \nu$ such that $k(\sigma(y) - y) = 0$ (in $T$).

Since $G$ is finite we may assume $k$ independent of $\sigma$, so $\sigma(ky - ky) = 0$ or $z = ky \in T^G = R$, and $y = z/k \in R$. Since the map $G \to G_\nu$ is an epimorphism then $[G_\nu:1] \leq [G:1] = [T:R]$. But the lemma shows that $[G_\nu:1] \geq [T_\nu:R_\nu] = [T:R]$. Hence $[G_\nu:1] = [T_\nu:R_\nu]$ and lemma 7 applies, hence $(f_\sigma)_\nu = 0$ and we are done.

### 3. Embedding of a separable algebra into a Galois extension

Let $S$ be a separable projective faithful $R$-algebra with rank $[S:R] = n$. We want to embed $S$ in an algebra $T$, Galois over $R$ with Galois group (isomorphic to) the symmetric group $S_n$ (the group of permutations of $\{a_1, \ldots, a_n\}$) with rank $[T:R] = n!$ such that $T \otimes_{S_n} = S$ where we consider $S_n$ embedded into $S_n$ as the subgroup leaving fixed the element $a_1$.

The $n$ different inclusions $\xi_j$ of $S_n$ will also give isomorphic copies of $S$. Call, for simplicity, $S^i = S \otimes S \otimes \cdots \otimes S$ $i$ times, and consider the sequence

$$R \to S \to S^2 \to S^3 \cdots$$

where $\xi_i: S^k \to S^{k+1}$ ($0 \leq i \leq k$) is defined by

$$\xi_i(s_1 \otimes \cdots \otimes s_k) = s_i \otimes \cdots \otimes s_1 \otimes s_{i+1} \otimes \cdots \otimes s_k$$

Define now maps $\mu_{ij}: S^k \to S^{k+1}$ by

$$\mu_{ij}(s_1 \otimes \cdots \otimes s_k) = s_i \otimes \cdots \otimes s_j \otimes s_{j+1} \otimes \cdots \otimes s_k \quad (0 \leq i, j \leq k, i \neq j)$$

call $N^k = \bigcap \ker \mu_{ij} \subseteq S^k$.

The algebra $T$ we want is $N^n$ and $S_n$ acts on $T$ induced by the permutations
of the factors in \( S^n \).

Since \( \mu_{ij} \) is the only \( \mu \) from \( S^2 \to S \), we have the splitting exact sequence

\[
0 \longrightarrow N^2 \longrightarrow S^2 \overset{\mu}{\longrightarrow} S \longrightarrow 0
\]

and \([S:R]=|S^2:S|=n\) implies \([N^2:S]=n-1\) and \(N^2\) is a projective separable \( S \)-algebra.

Let us prove first that \( N^r \) is projective separable \( R \)-algebra with rank and \([N^r:R]=n^{r-1}\)(since \(S \otimes N^{r-1}=\cap \text{Ker} \mu_{i,j}\) \( i\neq j\)) and \( \mu_{ij} \) induce \( \bar{\mu}_{ij}: S \otimes N^{r-1} \to N^{r-1} \). It is immediately verified that \( N^r=\cap \text{Ker} \bar{\mu}_{ij} \) and we get the exact sequence

\[
0 \longrightarrow N^r \longrightarrow S \otimes N^{r-1} \overset{\bar{\mu}}{\longrightarrow} \Sigma \otimes N^{r-1}
\]

where

\[
\bar{\mu} = \Sigma_{k=2} \Sigma_{l=1}^{n} \bar{\mu}_{hl}.
\]

If we prove \( \bar{\mu} \) is an epimorphism, since \([S:R]=n\), \([N^r-1:R]=\Pi_{0}^{n-2}(n-i)\) and the sequence splits, then \([N^r:R]=n[N^{r-1}:R]-(r-1)[N^{r-1}:R]=\Pi_{0}^{n-2}(n-i)\)

Since each \( \mu_{ij} \) is a multiplication map

\[
S^k = S^{k-1} \otimes S^{k-2}, \quad S^{k-1} \longrightarrow S^{k-1},
\]

\( S^k \) separable over \( S^{k-1} \) implies \( \text{Ker} \mu_{i,j} \) is an ideal in \( S^k \) generated by an idempotent \( 1-e_{i,j} \).

If

\[
e = \sum_{h} x_h \otimes y_h = e(S|R), \quad \text{then}
\]

\[
e_{i,j} = \sum_{h} x_h \otimes \cdots \otimes x_h \otimes \cdots y_h \otimes \cdots 1.
\]

Hence \( N^k=\cap \text{Ker} \mu_{i,j} \) is the ideal generated by \( E_k=\Pi (1-e_{i,j}) \). Hence \( N^k \) is a projective separable \( R \)-algebra.

We have \( \bar{\mu}_{ij}(e_{i,j})=1, \quad \bar{\mu}_{i}(e_{i,j})=e_{h-1,j-1} \) if \( h \neq j \). Since the map \( \bar{\mu} \) is an \( S^{r-1} \) homomorphism, to see it is onto it is enough to check the \( S^{r-1} \)-generators of \( \Sigma N^{r-1} \) are in \( \text{Im} \ \mu \). Those generators are

\[
F_j = (0, \cdots, 0, E_{r-1}, 0, \cdots, 0).
\]

Let

\[
k_j = e_{i,j} \cdot \varepsilon_0 E_{r-1},
\]

then

\[
\bar{\mu}(k_j) = (\bar{\mu}_{i,j}(k_j), \cdots, \bar{\mu}_{i,j}(k_j))
\]

but

\[
\bar{\mu}_{i,j}(k_j) = \bar{\mu}_{i,j}(e_{i,j}) \bar{\mu}_{i,j}(e_0 E_{r-1}) = E_{r-1}
\]
\[ \bar{\mu}(k_j) = e_{h-1,j-1} \cdot E_{r-1} = 0 \text{ (if } h+i) \]

hence \( \bar{\mu}(k_j) = F_j \) for every \( j \).

We want to prove now that \( T \) contains a copy of \( S \).

**Lemma 8.** The map \( S \rightarrow N^2 \subseteq S^2 \) defined by \( x \rightarrow (x \otimes 1)(1-e) \) is a monomorphism.

Proof. Let \( (s \otimes 1)(1-e) = 0 \). Since \( e \) is invariant under the permutation \( x \otimes y \rightarrow y \otimes x \), then \( (1 \otimes s)(1-e) = 0 \), hence \( (s \otimes 1)(1-e) = 0 \) and \( (s \otimes 1)(1-e) = 0 \) imply \( s \otimes 1 = 1 \otimes s \), hence \( s \in R \).

If \( k \in R \) and \( k(1-e) = 0 \), we have, for every

\[ x \in S \quad (1 \otimes x)k = (1 \otimes x)ke = k(1 \otimes x)e \]

\[ (x \otimes 1)k = (x \otimes 1)k \]

hence \( 1 \otimes k \cdot x = k \cdot x \otimes 1 \) so \( kx \in R \) and \( kS \subseteq R \). Since \( S \) is a projective \( R \)-algebra of rank \( n+1 \) then \( S = R \oplus C \) (as \( R \)-modules), \( C \) projective with rank and not zero, then \( kS \subseteq R \) implies \( kC = 0 \). Localizing, \( C \) is free hence \( k_C = 0 \) implies \( k _S = 0 \) hence \( k = 0 \).

**Lemma 9.** The maps \( \Gamma_{i,t} : N^i \rightarrow N^{i+t} \) defined by

\[ \Gamma_{i,t}(x_1 \otimes \cdots \otimes x_i) = (x_1 \otimes \cdots \otimes x_i \otimes 1 \otimes \cdots \otimes 1)E_{i+t} \]

are monomorphisms.

We already proved the lemma in the particular case \( S = N^1 \rightarrow N^2 \). Since \( (E_j \otimes 1)E_{j+1} = E_j \otimes 1 \), it will be enough to prove the lemma for \( t = 1 \).

Let \( V = N^2 = \text{Ker } \mu \), \( \mu : S^2 \rightarrow S \), and call \( V' = V \otimes S \cdots \otimes S V \). We have already seen that \( V \) is a projective faithful separable \( S \)-algebra with rank and \( [V : S] = n-1 \).

Repeating the process explained for \( S \) as an \( R \)-algebra to \( V \) as an \( S \)-algebra, call \( \tilde{\mu}_{i,j} \) the corresponding multiplication maps

\[ V^r \longrightarrow V^{r-1} \quad \text{and} \quad \tilde{N}^r = \bigcap \text{Ker } \tilde{\mu}_{i,j}. \]

we have monomorphisms

\[ \theta^r : V^r \rightarrow S^{r+1} \quad \text{defined by the composition} \quad V^r \rightarrow S^2 \otimes S \cdots \otimes S S^2 \rightarrow S^{r+1} \]

where each \( S^2 \) is an \( S \)-module by the action on the first factor, the second map being the canonical isomorphism. Hence

\[ \theta^r : V^r \longrightarrow S^{r-1} \]

\[ \overline{\mu}_{i,j} \downarrow \quad \mu_{i+1,j+1} \]

\[ \theta _{r-1} : V^{r-1} \longrightarrow S^r \]
commutes. The \( \mu_{ij} \)'s not appearing in this way are all zero on \( V^r \), then \( \mathcal{N}^r = N_{r+1}^r \).

In fact, \( \theta^r \) identifies \( V^r \) with \( \bigcap \text{Ker } \mu_{ij} \), and, \( \theta^{r-1} \mu_{ij} = \mu_{i+1,j+1} \theta^r \) shows that \( \theta^r \) induces the isomorphism \( \mathcal{N}^r \to N_{r+1}^r \).

We complete the proof of the lemma by induction over \([S:R]\). If \([S:R]=1\) then \( S=R \) and everything works.

Let \([S:R]=n\) and assume the result is true for every case \([U:W]<n\). Hence the lemma holds for \( V \) as an \( S \)-algebra, i.e., \( \mathcal{N}^r \to \mathcal{N}^{r+1} \) is monic, and so is \( N_{i+1}^i \to N_{i+2}^i \). We need then to check \( S=N^1 \to N^2 \), which was already proved.

We have then obtained a chain of algebras,

\[ R \subset S \subset N^2 \subset \cdots \subset N^n \]

where \( N^i \) is a projective faithful separable \( N^{i-1} \)-algebra with rank, \([N^i:N^{i-1}]=n-i+1\) (It also follows that \( N^M=0 \) for \( M>n \)).

Let \( \mathfrak{S}_n \) be the symmetric group acting as permutations of the factors of \( S^n \). Since \( N^n \) is invariant under \( \mathfrak{S}_n \) and it is generated by a unique idempotent \( E_n \), then \( E_n \) is invariant under \( \mathfrak{S}_n \). \( \mathfrak{S}_n \) induces a group of automorphisms of \( N^n \).

In the chain of algebras we considered before, \( R \) was identified with \( RE_n \).

Since \( N^n=N^{n-1} \) (corresponding to the construction for \( V=N^2 \) as an \( S \)-algebra) the group \( \mathfrak{S}_{n-1} \), acting on \( N^n \) as an \( S \)-algebra corresponds to the subgroup of \( \mathfrak{S}_n \) of those permutations which leave fixed the first factor. In the same way, \( \mathfrak{S}_j \) acts leaving fixed the first \( n-j \) factors.

We want to prove \( (N^n)^{\mathfrak{S}_{n-1}}=R \). Induction on \([S:R]\).

If \([S:R]=1\), \( R=S=N^1 \) and we have nothing to prove.

Assume it is true for \([S:R]<n\). Then it is true for \( V \) over \( S \), hence

\[(N^{n-1})^{\mathfrak{S}_{n-1}}=S, \quad \text{or} \quad (N^n)^{\mathfrak{S}_{n-1}}=S.\]

Assume \( \alpha \in N^n \) is invariant under \( \mathfrak{S}_n \).

In particular, it is invariant under \( \mathfrak{S}_{n-1} \), and our induction hypothesis implies \( \alpha \in \text{Im } (S) \).

We have two maps \( S \to V \), say \( \theta_1, \theta_2 \) where \( \theta_i(s)=\varepsilon_i(s)E_2 \).

Call \( \lambda: V \to N^n \) the inclusion defined above. Then

\[ \alpha = \lambda \cdot \theta_i(s) \quad \text{for some } s \in S. \]

Let \( \sigma \) be the permutation interchanging the two first factors. Then, easy computations show that \( \sigma(\alpha)=\lambda \cdot \theta_0(s) \), \( \lambda \) being a monomorphism, \( \alpha = \sigma(\alpha) \) implies \( \theta_i(s)=\theta_0(s) \), hence \( [\varepsilon_0(s)-\varepsilon_i(s)]E_2=0 \) but \( E_2=1-e, \ [\varepsilon_0(s)-\varepsilon_i(s)]e=0 \) shows that \( \varepsilon_0(s)=\varepsilon_i(s) \) in \( S^i \). Hence \( s \in R \) and we are done. The fact that \([N^*:R]=\mathfrak{S}_n:1\] shows that \( N^n \) is Galois in the sense of CHR.
Throughout this section we have been assuming that $S$ has a rank over $R$. If not, $R$ splits in a finite number of direct summands $R^K$ over which $S^K$ has rank $K^*(*)$. By embedding each $S_K$ into the corresponding $N^K$, then $N=\Sigma_K\oplus N^K$ will be Galois over $R$ with group $\Pi\Theta_K$ (direct product in which only the factors $\Theta_K$ for which $R_K\neq 0$ intervene).

In this case, $N$ is Galois in the sense defined in this paper but not in that of C-H-R, any more.

4. Universality

Suppose now $S$ has no proper idempotents. We have, as before $R\subseteq S\subseteq T$, $T$ obtained by the previous construction.

Let $h_1, \ldots, h_r$ be the minimal idempotents in $T$. Call $W_i=Th_i$, then all $W_i$ are $S$-isomorphic. Since the maps $R\rightarrow R h_i$ and $S\rightarrow S h_i$ are isomorphisms, then $W_i$ is a Galois extension of both $R$ and $S$.

We want to prove:

**Theorem 3.** If $S$ has no proper i.p., and $X$ is a Galois extension of $R$ containing $S$, there is an isomorphic copy $W$ of $W_i$ in $X$ such that $R\subseteq S\subseteq W\subseteq X$, i.e., $W_i$ is the Galois envelope of $S$ over $R$.

So, let $X$ be a Galois extension of $R$ containing $S$. If $X$ has proper idempotents, let $h_1, \ldots, h_s$ the minimal ones, $X=\Sigma X h_i$ and all $Y_i=X h_i$ are mutually isomorphic. By choosing isomorphisms $Y_i\rightarrow Y_i$ we obtain a subalgebra $Y$ of $X$, isomorphic to each $Y_i$, by taking the elements $(y, \lambda_1(y), \ldots, \lambda_n(y))$ in $\Sigma Y_i=X$.

We will prove that $Y$ contains $W$, isomorphic to each $W_i$.

Since $Y_i$ is a direct summand in $X$, then $Y_i$ (hence $Y$) is Galois over $R$ [6]. Since $Y$ has no i.p., $[G(Y/R):G(Y/S)]=n$ ($\S 2$), hence $G(Y/R)$ induces exactly $n$ different $R$-isomorphisms of $S$ into $Y$, say $\theta_1=\text{id}, \theta_2, \ldots, \theta_n$.

Define a map $\alpha: S^n\rightarrow Y$ by

\[
\alpha(s_1, \ldots, s_n) = \theta_1(s_1) \cdots \theta_n(s_n).
\]

Let $\overline{S}$ be the subalgebra of $Y$ generated by the copies of $S$. Hence $\alpha$ induces an epimorphism $\overline{\alpha}: S^n\rightarrow \overline{S}$. Now, we had

\[
T = S^n \cdot E, \quad E = \Pi(1-e_{ij}), \quad \text{and} \quad (1 \otimes 1 \otimes \cdots \otimes x_i \otimes 1 \otimes \cdots \otimes 1) e_{ij} = (1 \otimes \cdots \otimes x \otimes \cdots \otimes 1) e_{ij},
\]

so applying $\alpha$ we get, to every $x \in S$,

* This is an immediate consequence of [5] Prop. 4 and the fact that $S$ is a finitely generated projective $R$-module.
\[ \theta_i(x)\alpha(e_{ij}) = \theta_j(x)\alpha(e_{ij}) \]

but \( e_{ij} \) is an i.p. in \( \overline{S} \), contained in \( Y \), and \( Y \) has no i.p., hence

\[ \alpha(e_{ij}) = 0.1, \]

but \( \theta_i \) being different than \( \theta_j \), the previous equation shows \( \alpha(e_{ij}) \neq 1 \), then

\[ \alpha(E) = 1, \quad \text{and} \quad \alpha(1-E) = 0. \]

Hence \( \alpha \) induces an epimorphism \( \alpha_i : T \to \overline{S} \).

Since \( T = \Sigma T_h \), and \( \alpha_i \) is a ring homomorphism, \( \alpha_i(h_i) \) is an idempotent in \( \overline{S} \), hence 0 or 1, \( \alpha_i \) being an epimorphism implies \( \alpha_i(h_i) = 1 \) for some \( i \), hence \( \alpha_i(1-h_i) = \alpha_i(\Sigma j \neq i h_j) = 0 \) and \( \alpha_i \) induces an epimorphism \( \alpha_i : T_h \to \overline{S} \), which combined with the isomorphism \( W \to T_h \) gives \( W \to \overline{S} \).

But \( \alpha_\Sigma \) being an epimorphism shows that \( \overline{S} \) is \( R \)-separable. Since \( Y \) is \( R \)-projective, then \( Y \) is \( \overline{S} \)-projective and \( \overline{S} \) is an \( \overline{S} \)-direct summand in \( Y \), hence an \( R \)-direct summand and \( \overline{S} \) is \( R \)-projective.

But \( W \) being \( R \)-separable and \( \overline{S} \) \( R \)-projective imply \( \overline{S} \) is \( W \)-projective, hence \( \text{Ker} \ \alpha_\Sigma \) is generated by an i.p.; since \( W \) has no proper i.p. and \( \alpha_\Sigma \neq 0 \), then \( \text{Ker} \ \alpha_\Sigma = 0 \), and \( \alpha_\Sigma \) is an isomorphism.

**Remark.** The result extends easily to the case \( R \) has a finite number of idempotents.
