# STABILITY OF EXTREMAL KÄHLER MANIFOLDS 

Dedicated to Professor Shoshichi Kobayashi on his seventieth birthday

Toshiki MABUCHI

(Received January 15, 2003)

## 1. Introduction

In Donaldson's study [10] of asymptotic stability for polarized algebraic manifolds ( $M, L$ ), critical metrics originally defined by Zhang [39] (see also [22]) are referred to as balanced metrics and play a central role when the polarized algebraic manifolds admit Kähler metrics of constant scalar curvature. Let $T \cong\left(\mathbb{C}^{*}\right)^{k}$ be an algebraic torus in the identity component $\operatorname{Aut}^{0}(M)$ of the group of holomorphic automorphisms of $M$. In this paper, we define the concept of critical metrics relative to $T$, and as an application, choosing a suitable $T$, we shall show that a result in [26] on the asymptotic approximation of critical metrics (see [10], [39]) can be generalized to the case where $(M, L)$ admits an extremal Kähler metric in the polarization class. Then in our forthcoming paper [27], we shall show that a slight modification of the concept of stability (see Theorem A below) allows us to obtain the asymptotic stability of extremal Kähler manifolds even when the obstruction as in [26] does not vanish. In particular, by an argument similar to [10], an extremal Kähler metric in a fixed integral Kähler class on a projective algebraic manifold $M$ will be shown to be unique* up to the action of the group $\operatorname{Aut}^{0}(M)$.

## 2. Statement of results

Throughout this paper, we fix once for all an ample holomorphic line bundle $L$ on a connected projective algebraic manifold $M$. Let $H$ be the maximal connected linear algebraic subgroup of $\operatorname{Aut}^{0}(M)$, so that $\operatorname{Aut}^{0}(M) / H$ is an abelian variety. The corresponding Lie subalgebra of $H^{0}\left(M, \mathcal{O}\left(T^{1,0} M\right)\right)$ will be denoted by $\mathfrak{h}$. For the complete linear system $\left|L^{m}\right|, m \gg 1$, we consider the Kodaira embedding

$$
\Phi_{m}=\Phi_{\left|L^{m}\right|}: M \hookrightarrow \mathbb{P}^{*}\left(V_{m}\right), \quad m \gg 1,
$$

where $\mathbb{P}^{*}\left(V_{m}\right)$ denotes the set of all hyperplanes through the origin in $V_{m}:=$ $H^{0}\left(M, \mathcal{O}\left(L^{m}\right)\right)$. Put $N_{m}:=\operatorname{dim} V_{m}-1$. Let $n$ and $d$ be respectively the dimension

[^0]of $M$ and the degree of the image $M_{m}:=\Phi_{m}(M)$ in the projective space $\mathbb{P}^{*}\left(V_{m}\right)$. Put $W_{m}=\left\{\operatorname{Sym}^{d}\left(V_{m}\right)\right\}^{\otimes n+1}$. Then to the image $M_{m}$ of $M$, we can associate a nonzero element $\hat{M}_{m}$ in $W_{m}^{*}$ such that the corresponding element $\left[\hat{M}_{m}\right]$ in $\mathbb{P}^{*}\left(W_{m}\right)$ is the Chow point associated to the irreducible reduced algebraic cycle $M_{m}$ on $\mathbb{P}^{*}\left(V_{m}\right)$. Replacing $L$ by some positive integral multiple of $L$ if necessary, we fix an $H$-linearization of $L$, i.e., a lift to $L$ of the $H$-action on $M$ such that $H$ acts on $L$ as bundle isomorphisms covering the $H$-action on $M$. For an algebraic torus $T$ in $H$, this naturally induces a $T$-action on $V_{m}$ for each $m$. Now for each character $\chi \in \operatorname{Hom}\left(T, \mathbb{C}^{*}\right)$, we set
$$
V(\chi):=\left\{s \in V_{m} ; t \cdot s=\chi(t) s \text { for all } t \in T\right\} .
$$

Then we have mutually distinct characters $\chi_{1}, \chi_{2}, \ldots, \chi_{\nu_{m}} \in \operatorname{Hom}\left(T, \mathbb{C}^{*}\right)$ such that the vector space $V_{m}=H^{0}\left(M, \mathcal{O}\left(L^{m}\right)\right)$ is uniquely written as a direct sum

$$
\begin{equation*}
V_{m}=\bigoplus_{k=1}^{\nu_{m}} V\left(\chi_{k}\right) . \tag{2.1}
\end{equation*}
$$

Put $G_{m}:=\prod_{k=1}^{\nu_{m}} \operatorname{SL}\left(V\left(\chi_{k}\right)\right)$, and the associated Lie subalgebra of $\operatorname{sl}\left(V_{m}\right)$ will be denoted by $\mathfrak{g}_{m}$. More precisely, $G_{m}$ and $\mathfrak{g}_{m}$ possibly depend on the choice of the algebraic torus $T$, and if necessary, we denote these by $G_{m}(T)$ and $\mathfrak{g}_{m}(T)$, respectively. The $T$-action on $V_{m}$ is, more precisely, a right action, while we regard the $G_{m}$-action on $V_{m}$ as a left action. Since $T$ is Abelian, this $T$-action on $V_{m}$ can be regarded also as a left action.

The group $G_{m}$ acts diagonally on $V_{m}$ in such a way that, for each $k$, the $k$-th factor $\operatorname{SL}\left(V\left(\chi_{k}\right)\right)$ of $G_{m}$ acts just on the $k$-th factor $V\left(\chi_{k}\right)$ of $V_{m}$. This induces a natural $G_{m}$-action on $W_{m}$ and also on $W_{m}^{*}$.

Definition 2.2. (a) The subvariety $M_{m}$ of $\mathbb{P}^{*}\left(V_{m}\right)$ is said to be stable relative to $T$ or semistable relative to $T$, according as the orbit $G_{m} \cdot \hat{M}_{m}$ is closed in $W_{m}^{*}$ or the closure of $G_{m} \cdot \hat{M}_{m}$ in $W_{m}^{*}$ does not contain the origin of $W_{m}^{*}$.
(b) Let $\mathfrak{t}_{c}$ denote the Lie subalgebra of the maximal compact subgroup $T_{C}$ of $T$, and as a real Lie subalgebra of the complex Lie algebra $\mathfrak{t}$, we define $\mathfrak{t}_{\mathbb{R}}:=\sqrt{-1} \mathfrak{t}_{c}$.

Take a Hermitian metric for $V_{m}$ such that $V\left(\chi_{k}\right) \perp V\left(\chi_{l}\right)$ if $k \neq l$. Put $N_{m}:=$ $\operatorname{dim} V_{m}-1$ and $n_{k}:=\operatorname{dim} V\left(\chi_{k}\right)$. We then set

$$
l(k, i):=(i-1)+\sum_{j=1}^{k-1} n_{j}, \quad i=1,2, \ldots, n_{k} ; k=1,2, \ldots, \nu_{m},
$$

where the right-hand side denotes $i-1$ in the special case $k=1$. Let $\|\|$ denote the Hermitian norm for $V_{m}$ induced by the Hermitian metric. Take a $\mathbb{C}$-basis $\left\{s_{0}, s_{1}, \ldots, s_{N_{m}}\right\}$ for $V_{m}$.

Definition 2.3. We say that $\left\{s_{0}, s_{1}, \ldots, s_{N_{m}}\right\}$ is an admissible normal basis for $V_{m}$ if there exist positive real constants $b_{k}, k=1,2, \ldots, \nu_{m}$, and a $\mathbb{C}$-basis $\left\{s_{k, i} ; i=\right.$ $\left.1,2, \ldots, n_{k}\right\}$ for $V\left(\chi_{k}\right)$, with $\sum_{k=1}^{\nu_{m}} n_{k} b_{k}=N_{m}+1$, such that
(1) $s_{l(k, i)}=s_{k, i}, \quad i=1,2, \ldots, n_{k} ; k=1,2, \ldots, \nu_{m}$;
(2) $s_{l} \perp s_{l^{\prime}}$ if $l \neq l^{\prime}$;
(3) $\left\|s_{k, i}\right\|^{2}=b_{k}, \quad i=1,2, \ldots, n_{k} ; k=1,2, \ldots, \nu_{m}$.

Then the real vector $b:=\left(b_{1}, b_{2}, \ldots, b_{\nu_{m}}\right)$ is called the index of the admissible normal basis $\left\{s_{0}, s_{1}, \ldots, s_{N_{m}}\right\}$ for $V_{m}$.

We now specify a Hermitian metric on $V_{m}$. For the maximal compact subgroup $T_{c}$ of $T$ above, let $\mathcal{S}$ be the set $(\neq \emptyset)$ of all $T_{c}$-invariant Kähler forms in the class $c_{1}(L)_{\mathbb{R}}$. Let $\omega \in \mathcal{S}$, and choose a Hermitian metric $h$ for $L$ such that $\omega=c_{1}(L ; h)$. Define a Hermitian metric on $V_{m}$ by

$$
\begin{equation*}
\left(s, s^{\prime}\right)_{L^{2}}:=\int_{M}\left(s, s^{\prime}\right)_{h^{m}} \omega^{n}, \quad s, s^{\prime} \in V_{m} \tag{2.4}
\end{equation*}
$$

where $\left(s, s^{\prime}\right)_{h^{m}}$ denotes the function on $M$ obtained as the pointwise inner product of $s, s^{\prime}$ by the Hermitian metric $h^{m}$ on $L^{m}$. Now, let us consider the situation that $V_{m}$ has the Hermitian metric (2.4). Then

$$
V\left(\chi_{k}\right) \perp V\left(\chi_{l}\right), \quad k \neq l,
$$

and define a maximal compact subgroup $\left(G_{m}\right)_{c}$ of $G_{m}$ by $\left(G_{m}\right)_{c}:=\prod_{k=1}^{\nu_{m}} \mathrm{SU}\left(V\left(\chi_{k}\right)\right)$. Again by this Hermitian metric $(,)_{L^{2}}$, let $\left\{s_{0}, s_{1}, \ldots, s_{N_{m}}\right\}$ be an admissible normal basis for $V_{m}$ of a given index $b$. Put

$$
\begin{equation*}
E_{\omega, b}:=\sum_{i=0}^{N_{m}}\left|s_{i}\right|_{h^{m}}^{2}, \tag{2.5}
\end{equation*}
$$

where $|s|_{h^{m}}:=(s, s)_{h^{m}}$ for all $s \in V_{m}$. Then $E_{\omega, b}$ depends only on $\omega$ and $b$. Namely, once $\omega$ and $b$ are fixed, $E_{\omega, b}$ is independent of the choice of an admissible normal basis for $V\left(\chi_{k}\right)$ of index $b$. Fix a positive integer $m$ such that $L^{m}$ is very ample.

Definition 2.6. An element $\omega$ in $\mathcal{S}$ is called a critial metric relative to $T$, if there exists an admissible normal basis $\left\{s_{0}, s_{1}, \ldots, s_{N_{m}}\right\}$ for $V_{m}$ such that the associated function $E_{\omega, b}$ on $M$ is constant for the index $b$ of the admissible normal basis. This generalizes a critical metric of Zhang [39] (see also [5]) who treated the case $T=\{1\}$. If $\omega$ is a critical metric relative to $T$, then by integrating the equality (2.5) over $M$, we see that the constant $E_{\omega, b}$ is $\left(N_{m}+1\right) / c_{1}(L)^{n}[M]$.

For the centralizer $Z_{H}(T)$ of $T$ in $H$, let $Z_{H}(T)^{0}$ be its identity component. For $m$ as above, the following generalization of a result in [39] is crucial to our study of
stability:
Theorem A. The subvariety $M_{m}$ of $\mathbb{P}\left(V_{m}\right)$ is stable relative to $T$ if and only if there exists a critical metric $\omega \in \mathcal{S}$ relative to $T$. Moreover, for a fixed index $b, a$ critical metric $\omega$ in $\mathcal{S}$ relative to $T$ with constant $E_{\omega, b}$ is unique up to the action of $Z_{H}(T)^{0}$.

We now fix a maximal compact connected subgroup $K$ of $H$. The corresponding Lie subalgebra of $\mathfrak{h}$ is denoted by $\mathfrak{k}$. Let $\mathcal{S}_{K}$ denote the set of all Kähler forms $\omega$ in the class $c_{1}(L)_{\mathbb{R}}$ such that the identity component of the group of the isometries of $(M, \omega)$ coincides with $K$. Then $\mathcal{S}_{K} \neq \emptyset$, and an extremal Kähler metric, if any, in the class $c_{1}(L)_{\mathbb{R}}$ is always in $H$-orbits of elements of $\mathcal{S}_{K}$. For each $\omega \in \mathcal{S}_{K}$, we write

$$
\omega=\frac{\sqrt{-1}}{2 \pi} \sum_{\alpha, \beta} g_{\alpha \bar{\beta}} d z^{\alpha} \wedge d z^{\bar{\beta}}
$$

in terms of a system $\left(z^{1}, \ldots, z^{n}\right)$ of holomorphic local coordinates on $M$. let $\mathcal{K}_{\omega}$ be the space of all real-valued smooth functions $u$ on $M$ such that $\int_{M} u \omega^{n}=0$ and that

$$
\operatorname{grad}_{\omega}^{\mathbb{C}} u:=\frac{1}{\sqrt{-1}} \sum_{\alpha, \beta} g^{\bar{\beta} \alpha} \frac{\partial u}{\partial z^{\bar{\beta}}} \frac{\partial}{\partial z^{\alpha}}
$$

is a holomorphic vector field on $M$. Then $\mathcal{K}_{\omega}$ forms a real Lie subalgebra of $\mathfrak{h}$ by the Poisson bracket for $(M, \omega)$. We then have the Lie algebra isomorphism

$$
\mathcal{K}_{\omega} \cong \mathfrak{k}, \quad u \leftrightarrow \operatorname{grad}_{\omega}^{\mathbb{C}} u .
$$

For the space $C^{\infty}(M)_{\mathbb{R}}$ of real-valued smooth functions on $M$, we consider the inner product defined by $\left(u_{1}, u_{2}\right)_{\omega}:=\int_{M} u_{1} u_{2} \omega^{n}$ for $u_{1}, u_{2} \in C^{\infty}(M)_{\mathbb{R}}$. Let pr: $C^{\infty}(M)_{\mathbb{R}} \rightarrow$ $\mathcal{K}_{\omega}$ be the orthogonal projection. Let $\mathfrak{z}$ be the center of $\mathfrak{k}$. Then the vector field

$$
\mathcal{V}:=\operatorname{grad}_{\omega}^{\mathbb{C}} \operatorname{pr}\left(\sigma_{\omega}\right) \in \mathfrak{z}
$$

is callled the extremal Kähler vector field of $(M, \omega)$, where $\sigma_{\omega}$ denotes the scalar curvature of $\omega$. Then $\mathcal{V}$ is independent of the choice of $\omega$ in $\mathcal{S}$, and satisfies $\exp (2 \pi \gamma \mathcal{V})=$ 1 for some positive integer $\gamma$ (cf. [13], [32]). Next, since we have an $H$-linearization of $L$, there exists a natural inclusion $H \subset \mathrm{GL}\left(V_{m}\right)$. By passing to the Lie algebras, we obtain

$$
\mathfrak{h} \subset \mathfrak{g l}\left(V_{m}\right) .
$$

Take a Hermitian metric $h$ for $L$ such that the corresponding first Chern form $c_{1}(L ; h)$ is $\omega$. As in [23, (1.4.1)], the infinitesimal $\mathfrak{h}$-action on $L$ induces an infinitesimal
$\mathfrak{h}$-action on the complexification $\mathcal{H}_{m}^{\mathbb{C}}$ of the space of all Hermitian metrics $\mathcal{H}_{m}$ on the line bundle $L^{m}$. The Futaki-Morita character $F: \mathfrak{h} \rightarrow \mathbb{C}$ is given by

$$
F(\mathcal{Y}):=\frac{\sqrt{-1}}{2 \pi} \int_{M} h^{-1}(\mathcal{Y} h) \omega^{n},
$$

which is independent of the choice of $h$ (see for instance [15]). For the identity component $Z$ of the center of $K$, we consider its complexification $Z^{\mathbb{C}}$ in $H$. Then the corresponding Lie algebra is just the complexification $\mathfrak{z}^{\mathbb{C}}$ of $\mathfrak{z}$ above. We now consider the set $\Delta$ of all algebraic tori in $Z^{\mathbb{C}}$. Let $T \in \Delta$. Put

$$
q:=\frac{1}{m} .
$$

For $\omega=c_{1}(L ; h) \in \mathcal{S}_{K}$, we consider the Hermitian metric (2.4) for $V_{m}$. We then choose an admissible normal basis $\left\{s_{0}, s_{1}, \ldots, s_{N_{m}}\right\}$ for $V_{m}$ of index $(1,1, \ldots, 1)$. By the asymptotic expansion of Tian-Zelditch (cf. [33], [38]; see also [4]) for $m \gg 1$, there exist real-valued smooth functions $a_{k}(\omega), k=1,2, \ldots$, on $M$ such that

$$
\begin{equation*}
\frac{n!}{m^{n}} \sum_{j=0}^{N_{m}}\left|s_{j}\right|_{h^{m}}^{2}=1+a_{1}(\omega) q+a_{2}(\omega) q^{2}+\cdots \tag{2.7}
\end{equation*}
$$

Then $a_{1}(\omega)=\sigma_{\omega} / 2$ by a result of $\operatorname{Lu}$ [20]. Let $\mathcal{Y} \in \mathfrak{t}_{\mathbb{R}}$, and put $g:=\exp ^{\mathbb{C}} \mathcal{Y} \in T$, where the element $\exp (\mathcal{Y} / 2)$ in $T$ is written as $\exp ^{\mathbb{C}} \mathcal{Y}$ by abuse of terminology. Recall that the $T$-action on $V_{m}$ is a right action, though it can be viewed also as a left action. Put $h_{g}:=h \cdot g$ for simplicity. Using the notation in Definition 2.3, we write $s_{k, i}=s_{l(k, i)}$, $k=1,2, \ldots, \nu_{m} ; i=1,2, \ldots, n_{k}$. Then for a fixed $k, \int_{M}\left|s_{k, i}\right|_{h_{g}^{m}}^{2} g^{*} \omega^{n}=\left|\chi_{k}\left(\exp ^{\mathbb{C}} \mathcal{Y}\right)\right|^{-2}$ is independent of the choice of $i$. Put

$$
Z(q, \omega ; \mathcal{Y}):=\frac{n!}{m^{n}} \sum_{j=0}^{N_{m}}\left|s_{j}\right|_{h_{g}^{m}}^{2}=g^{*}\left\{\frac{n!}{m^{n}} \sum_{k=1}^{\nu_{m}}\left|\chi_{k}\left(\exp ^{\mathbb{C}} \mathcal{Y}\right)\right|^{-2} \sum_{i=1}^{n_{k}}\left|s_{k, i}\right|_{h^{m}}^{2}\right\}, \quad \mathcal{Y} \in \mathfrak{t}_{\mathbb{R}} .
$$

For extremal Kähler manifolds, the following generalization of [26] allows us to approximate arbitrarily some critical metrics relative to $T$ :

Theorem B. Let $\omega_{0}=c_{1}\left(L ; h_{0}\right)$ be an extremal Kähler metric in the class $c_{1}(L)_{\mathbb{R}}$ with extremal Kähler vector field $\mathcal{V}$. Then for some $T \in \Delta$, there exist a sequence of vector fields $\mathcal{Y}_{k} \in \mathfrak{t}_{\mathbb{R}}$, a formal power series $C_{q}$ in $q$ with real coefficients ( $c f$. Section 6), and smooth real-valued functions $\varphi_{k}, k=1,2, \ldots$, on $M$ such that

$$
\begin{equation*}
Z(q, \omega(l) ; \mathcal{Y}(l))=C_{q}+0\left(q^{l+2}\right) \tag{2.8}
\end{equation*}
$$

where $\mathcal{Y}(l):=(\sqrt{-1} \mathcal{V} / 2) q^{2}+\sum_{k=1}^{l} q^{k+2} \mathcal{Y}_{k}, h(l):=h_{0} \exp \left(-\sum_{k=1}^{l} q^{k} \varphi_{k}\right)$, and $\omega(l):=$ $c_{1}(L ; h(l))$.

The equality (2.8) above means that there exists a positive real constant $A_{l}$ independent of $q$ such that $\left\|Z(q, \omega(l) ; \mathcal{Y}(l))-C_{q}\right\|_{C^{0}(M)} \leq A_{1} q^{l+2}$ for all $q$ with $0 \leq q \leq 1$. By [38], for every nonnegative integer $j$, a choice of a larger constant $A=A_{j, l}>0$ keeps Theorem B still valid even if the $C^{0}(M)$-norm is replaced by the $C^{j}(M)$-norm.

## 3. A stability criterion

In this section, some stability criterion will be given as a preliminary. In a forthcoming paper [27], we actually use a stronger version of Theorem 3.2 which guarantees the stability only by checking the closedness of orbits through a point for special one-parameter subgroups "perpendicular" to the isotropy subgroup. Now, for a connected reductive algebraic group $G$, defined over $\mathbb{C}$, we consider a representation of $G$ on an $N$-dimensional complex vector space $W$. We fix a maximal compact subgroup $G_{c}$ of $G$. Moreover, let $\mathbb{C}^{*}$ be a one-dimensional algebraic torus with the maximal compact subgroup $S^{1}$.

Definition 3.1. (a) An algebraic group homomorphism $\lambda: \mathbb{C}^{*} \rightarrow G$ is said to be a special one-parameter subgroup of $G$, if the image $\lambda\left(S^{1}\right)$ is contained in $G_{c}$.
(b) A point $w \neq 0$ in $W$ is said to be stable, if the orbit $G \cdot w$ is closed in $W$.

Later, we apply the following stability criterion to the case where $W=W_{m}^{*}$ and $G=G_{m}$. Let $w \neq 0$ be a point in $W$.

Theorem 3.2. A point $w$ as above is stable if and only if there exists a point $w^{\prime}$ in the orbit $G \cdot w$ of $w$ such that $\lambda\left(\mathbb{C}^{*}\right) \cdot w^{\prime}$ is closed in $W$ for every special oneparameter subgroup $\lambda: \mathbb{C}^{*} \rightarrow G$ of $G$.

Proof. We prove this by induction on $\operatorname{dim}(G \cdot w)$. If $\operatorname{dim}(G \cdot w)=0$, the statement of the above theorem is obviously true. Hence, fixing a positive integer $k$, assume that the statement is true for all $0 \neq w \in W$ such that $\operatorname{dim}(G \cdot w)<k$. Now, let $0 \neq w \in W$ be such that $\operatorname{dim}(G \cdot w)=k$, and the proof is reduced to showing the statement for such a point $w$. Let $\Sigma(G)$ be the set of all special one-parameter subgroups of $G$. Fix a $G_{c}$-invariant Hermitian metric $\|\|$ on $W$. The proof is divided into three steps:

Step 1. First, we prove "only if" part of Theorem 3.2. Assume that $w$ is stable. Since $G \cdot w$ is closed in $W$, the nonnegative function on $G \cdot w$ defined by

$$
\begin{equation*}
G \cdot w \ni g \cdot w \mapsto\|g \cdot w\| \in \mathbb{R}, \quad g \in G \tag{3.3}
\end{equation*}
$$

has a critical point at some point $w^{\prime}$ in $G \cdot w$. Let $\lambda \in \Sigma(G)$, and it suffices to show the closedness of $\lambda\left(\mathbb{C}^{*}\right) \cdot w^{\prime}$ in $W$. We may assume that $\operatorname{dim} \lambda\left(\mathbb{C}^{*}\right) \cdot w^{\prime}>0$. Then by using the coordinate system associated to an orthonormal basis for $W$, we can write
$w^{\prime}$ as $\left(w_{0}^{\prime}, \ldots, w_{r}^{\prime}, 0, \ldots, 0\right)$ in such a way that $w_{\alpha}^{\prime} \neq 0$ for all $0 \leq \alpha \leq r$ and that

$$
\lambda\left(e^{t}\right) \cdot w^{\prime}=\left(e^{t \gamma_{0}} w_{0}^{\prime}, \ldots, e^{t \gamma_{r}} w_{r}^{\prime}, 0, \ldots, 0\right), \quad t \in \mathbb{C}
$$

where $\gamma_{\alpha}, \alpha=0,1, \ldots, r$, are integers independent of the choice of $t$ in $\mathbb{C}$. Since the closed orbit $G \cdot w$ does not contain the origin of $W$, the inclusion $\lambda\left(\mathbb{C}^{*}\right) \cdot w^{\prime} \subset$ $G \cdot w$ shows that $r \geq 1$ and that the coincidence $\gamma_{0}=\gamma_{1}=\cdots=\gamma_{r}$ cannot occur. In particular,

$$
f(t):=\log \left\|\lambda\left(e^{t}\right) \cdot w^{\prime}\right\|^{2}=\log \left(e^{2 t \gamma_{0}}\left|w_{0}^{\prime}\right|^{2}+e^{2 t \gamma_{1}}\left|w_{1}^{\prime}\right|^{2}+\cdots+e^{2 t \gamma_{r}}\left|w_{r}^{\prime}\right|^{2}\right), \quad t \in \mathbb{R},
$$

satisfies $f^{\prime \prime}(t)>0$ for all $t$. Moreover, since the function in (3.3) has a critical point at $w^{\prime}$, we have $f^{\prime}(0)=0$. It now follows that $\lim _{t \rightarrow+\infty} f(t)=+\infty$ and $\lim _{t \rightarrow-\infty} f(t)=$ $+\infty$. Hence $\lambda\left(\mathbb{C}^{*}\right) \cdot w^{\prime}$ is closed in $W$, as required.

Step 2. To prove "if" part of Theorem 3.2, we may assume that $w=w^{\prime}$ without loss of generality. Hence, suppose that $\lambda\left(\mathbb{C}^{*}\right) \cdot w$ is closed in $W$ for every $\lambda \in \Sigma(G)$. It then suffices to show that $G \cdot w$ is closed in $W$. For contradiction, assume that $G \cdot w$ is not closed in $W$. Since the closure of $G \cdot w$ in $W$ always contains a closed orbit $O_{1}$ in $W$, by $\operatorname{dim} O_{1}<\operatorname{dim}(G \cdot w)=k$, the induction hypothesis shows that there exists a point $\hat{w} \in O_{1}$ such that

$$
\begin{equation*}
\lambda\left(\mathbb{C}^{*}\right) \cdot \hat{w} \text { is closed in } W \text { for every } \lambda \in \Sigma(G) . \tag{3.4}
\end{equation*}
$$

Moreover, there exist elements $g_{i}, i=1,2, \ldots$, in $G$ such that $g_{i} \cdot w$ converges to $\hat{w}$ in $W$. Then for each $i$, we can write $g_{i}=\kappa_{i}^{\prime} \cdot \exp \left(2 \pi A_{i}\right) \cdot \kappa_{i}$ for some $\kappa_{i}, \kappa_{i}^{\prime} \in G_{c}$ and for some $A_{i} \in \mathfrak{a}$, where $2 \pi \sqrt{-1} \mathfrak{a}$ is the Lie algebra of some maximal compact torus in $G_{c}$. Let $2 \pi \sqrt{-1} \mathfrak{a}_{\mathbb{Z}}$ be the kernel of the exponential map of the Lie algebra $2 \pi \sqrt{-1} \mathfrak{a}$, and put $\mathfrak{a}_{\mathbb{Q}}:=\mathfrak{a}_{\mathbb{Z}} \otimes \mathbb{Q}$. Replacing $\left\{\kappa_{i}\right\}$ by its subsequence if necessary, we may assume that

$$
\begin{equation*}
\kappa_{i} \rightarrow \kappa_{\infty} \quad \text { and } \quad\left\{\exp \left(2 \pi A_{i}\right) \cdot \kappa_{i}\right\} \cdot w \rightarrow w_{\infty}, \quad \text { as } i \rightarrow \infty \tag{3.5}
\end{equation*}
$$

for some $\kappa_{\infty} \in G_{c}$ and $w_{\infty} \in G_{c} \cdot \hat{w}$. Then by (3.4), the orbit $\lambda\left(\mathbb{C}^{*}\right) \cdot w_{\infty}$ is also closed in $W$ for every $\lambda \in \Sigma(G)$. Let $\mathfrak{a}_{\infty}$ denote the Lie subalgebra of $\mathfrak{a}$ consisting of all elements in $\mathfrak{a}$ whose associated vector fields on $W$ vanish at $\kappa_{\infty} \cdot w$. For a Euclidean metric on $\mathfrak{a}$ induced from a suitable bilinear form on $\mathfrak{a}_{\mathbb{Q}}$ defined over $\mathbb{Q}$, we write $\mathfrak{a}$ as a direct sum $\mathfrak{a}_{\infty}^{\perp} \oplus \mathfrak{a}_{\infty}$, where $\mathfrak{a}_{\infty}^{\perp}$ is the orthogonal complement of $\mathfrak{a}_{\infty}$ in $\mathfrak{a}$. Let $\bar{A}_{i}$ be the image of $A_{i}$ under the orthogonal projection

$$
\operatorname{pr}_{1}: \mathfrak{a}\left(=\mathfrak{a}_{\infty}^{\perp} \oplus \mathfrak{a}_{\infty}\right) \rightarrow \mathfrak{a}_{\infty}^{\perp}, \quad A \mapsto \bar{A}:=\operatorname{pr}_{1}(A) .
$$

Note that $\left\{\exp \left(2 \pi A_{i}\right) \cdot \kappa_{\infty}\right\} \cdot w=\left\{\exp \left(2 \pi \bar{A}_{i}\right) \cdot \kappa_{\infty}\right\} \cdot w$. Hence,

$$
\begin{equation*}
\limsup _{i \rightarrow \infty}\left\|\exp \left\{2 \pi \operatorname{Ad}\left(\kappa_{\infty}^{-1}\right) \bar{A}_{i}\right\} \cdot w\right\|=\underset{i \rightarrow \infty}{\limsup }\left\|\left\{\exp \left(2 \pi A_{i}\right) \cdot \kappa_{\infty}\right\} \cdot w\right\| \tag{3.6}
\end{equation*}
$$

$$
\leq \lim _{i \rightarrow \infty}\left\|\left\{\exp \left(2 \pi A_{i}\right) \cdot \kappa_{i}\right\} \cdot w\right\|=\left\|w_{\infty}\right\|<+\infty
$$

Step 3. Since $\lambda\left(\mathbb{C}^{*}\right) \cdot w$ is closed in $W$ for every $\lambda \in \Sigma(G)$, by the boundedness in (3.6), $\left\{\bar{A}_{i}\right\}$ is a bounded sequence in $\mathfrak{a}_{\infty}^{\perp}$ (see Remark 3.7 below). Hence, for some element $A_{\infty}$ in $\mathfrak{a}_{\infty}^{\perp}$, replacing $\left\{\bar{A}_{i}\right\}$ by its subsequence if necessary, we may assume that $\bar{A}_{i} \rightarrow A_{\infty}$ as $i \rightarrow \infty$. Then by (3.5),

$$
w_{\infty}=\lim _{i \rightarrow \infty}\left\{\exp \left(2 \pi \bar{A}_{i}\right) \cdot \kappa_{i}\right\} \cdot w=\left\{\exp \left(2 \pi \bar{A}_{\infty}\right) \cdot \kappa_{\infty}\right\} \cdot w
$$

Since we have $\exp \left(2 \pi \bar{A}_{\infty}\right) \in G$, the point $w_{\infty}$ in $O_{1}$ belongs to the orbit $G \cdot w$. This contradicts $O_{1} \cap(G \cdot w)=\emptyset$, as required. The proof of Lemma 3.2 is now complete.

Remark 3.7. The boundedness of the sequence $\left\{\bar{A}_{i}\right\}$ in $\mathfrak{a}_{\infty}^{\perp}$ in Step 3 above can be seen as follows: For contradiction, we assume that the sequence $\left\{\bar{A}_{i}\right\}$ is unbounded. Put $v:=\kappa_{\infty} \cdot w$ for simplicity. Then by (3.6), we first observe that

$$
\begin{equation*}
\limsup _{i \rightarrow \infty}\left\|\exp \left(2 \pi \bar{A}_{i}\right) \cdot v\right\|<+\infty \tag{3.8}
\end{equation*}
$$

Since $2 \pi \sqrt{-1} \mathfrak{a}_{\infty}$ is the Lie algebra of the isotropy subgroup of the compact torus $\exp (2 \pi \sqrt{-1} \mathfrak{a})$ at $v$, both $\mathfrak{a}_{\infty}$ and $\mathfrak{a}_{\infty}^{\perp}$ are defined over $\mathbb{Q}$ in $\mathfrak{a}$. By choosing a complex coordinate system of $W$, we can write $v$ as $\left(v_{0}, \ldots, v_{r}, 0, \ldots, 0\right)$ for some integer $r$ with $0 \leq r \leq \operatorname{dim} W-1$ such that $v_{\alpha} \neq 0$ for all $0 \leq \alpha \leq r$ and that

$$
\begin{equation*}
\exp (2 \pi \bar{A}) \cdot v=\left(e^{2 \pi \chi_{0}(\bar{A})} v_{0}, \ldots, e^{2 \pi \chi_{r}(\bar{A})} v_{r}, 0, \ldots, 0\right), \quad \bar{A} \in \mathfrak{a}_{\infty}^{\perp} \tag{3.9}
\end{equation*}
$$

where $\chi_{\alpha}: \mathfrak{a}_{\infty}^{\perp} \rightarrow \mathbb{R}, \alpha=0,1, \ldots, r$, are additive characters defined over $\mathbb{Q}$. Put $n:=\operatorname{dim}_{\mathbb{R}} \mathfrak{a}_{\infty}^{\perp}$, and let $\left(\mathfrak{a}_{\infty}^{\perp}\right)_{\mathbb{Q}}$ denote the set of all rational points in $\mathfrak{a}_{\infty}^{\perp}$. Let us now identify

$$
\mathfrak{a}_{\infty}^{\perp}=\mathbb{R}^{n} \quad \text { and } \quad\left(\mathfrak{a}_{\infty}^{\perp}\right)_{\mathbb{Q}}=\mathbb{Q}^{n}
$$

as vector spaces. Since the orbit $\lambda\left(\mathbb{C}^{*}\right) \cdot w$ is closed in $W$ for all special one-parameter subgroups $\lambda: \mathbb{C}^{*} \rightarrow G$ of $G$, the same thing is true also for $\lambda\left(\mathbb{C}^{*}\right) \cdot v$. Hence,

$$
\begin{equation*}
\mathbb{Q}^{n} \backslash\{0\} \subset \bigcup_{\alpha, \beta=0}^{r} U_{\alpha \beta} \tag{3.10}
\end{equation*}
$$

where $U_{\alpha \beta}:=\left\{A \in \mathfrak{a} ; \chi_{\alpha}(A)>0>\chi_{\beta}(A)\right\}$. Note that the boundaries of the open sets $U_{\alpha \beta}, 1 \leq \alpha \leq r, 1 \leq \beta \leq r$, in $\mathbb{R}^{n}$ sit in the union of $\mathbb{Q}$-hyperplanes

$$
H_{\alpha}:=\left\{\chi_{\alpha}=0\right\}, \quad \alpha=0,1, \ldots, r
$$

in $\mathbb{R}^{r}$. Since an intersection of any finite number of hyperplanes $H_{\alpha}, \alpha=0,1, \ldots, r$, has dense rational points, (3.10) above easily implies

$$
\begin{equation*}
\mathbb{R}^{n} \backslash\{0\}=\bigcup_{\alpha, \beta=0}^{r} U_{\alpha \beta} \tag{3.11}
\end{equation*}
$$

Replacing $\left\{\bar{A}_{i}\right\}$ by its suitable subsequence if necessary, we may assume that there exists an element $A_{\infty}$ in $\mathfrak{a}_{\infty}^{\perp}\left(=\mathbb{R}^{n}\right)$ with $\left\|A_{\infty}\right\|_{\mathfrak{a}}=1$ such that

$$
\lim _{i \rightarrow \infty} \frac{\bar{A}_{i}}{\left\|\bar{A}_{i}\right\|_{\mathfrak{a}}}=A_{\infty}
$$

where $\left\|\|_{\mathfrak{a}}\right.$ denotes the Euclidean norm for $\mathfrak{a}$ as in Step 2 in the proof of Theorem 3.2. By (3.11), there exist $\alpha, \beta \in\{0,1, \ldots, r\}$ such that $A_{\infty} \in U_{\alpha \beta}$, and in particular $\chi_{\alpha}\left(A_{\infty}\right)>0$. On the other hand, $\lim \sup _{i \rightarrow \infty}\left\|\bar{A}_{i}\right\|_{\mathfrak{a}}=+\infty$ by our assumption. Thus,

$$
\limsup _{i \rightarrow \infty} \chi_{\alpha}\left(\bar{A}_{i}\right)=\underset{i \rightarrow \infty}{\limsup }\left\{\left\|\bar{A}_{i}\right\|_{\mathfrak{a}} \cdot \chi_{\alpha}\left(\bar{A}_{i} /\left\|\bar{A}_{i}\right\|_{\mathfrak{a}}\right)\right\}=\left(\limsup _{i \rightarrow \infty}\left\|\bar{A}_{i}\right\|_{\mathfrak{a}}\right) \chi_{\alpha}\left(A_{\infty}\right)=+\infty,
$$

in contradiction to (3.8) and (3.9), as required.

## 4. The Chow norm

Take an algebraic torus $T \subset \operatorname{Aut}^{0}(M)$, and let $\iota: \operatorname{SL}\left(V_{m}\right) \rightarrow \operatorname{PGL}\left(V_{m}\right)$ be the nat-
 embedding $\Phi_{m}: M \hookrightarrow \mathbb{P}^{*}\left(V_{m}\right), m \gg 1$. In this section, we fix a $\tilde{T}_{c}$-invariant Hermitian metric $\rho$ on $V_{m}$, where $\tilde{T}_{c}$ is the maximal compact subgroup of $\tilde{T}:=\iota^{-1}(T)$. Obviously, in terms of this metric, $V\left(\chi_{k}\right) \perp V\left(\chi_{l}\right)$ if $k \neq l$. Using Deligne's pairings (cf. [8, 8.3]), Zhang ([39, 1.5]) defined a special type of norm on $W_{m}^{*}$, called the Chow norm, as a nonnegative real-valued function

$$
\begin{equation*}
W_{m}^{*} \ni w \longmapsto\|w\|_{\mathrm{CH}(\rho)} \in \mathbb{R}_{\geq 0}, \tag{4.1}
\end{equation*}
$$

with very significant properties described below. First, this is a norm, so that it has the only zero at the origin satisfying the homogeneity condition

$$
\|c w\|_{\mathrm{CH}(\rho)}=|c| \cdot\|w\|_{\mathrm{CH}(\rho)} \quad \text { for all }(c, w) \in \mathbb{C} \times W_{m}^{*} .
$$

For the group $\operatorname{SL}\left(V_{m}\right)$, we consider the maximal compact subgroup $\operatorname{SU}\left(V_{m} ; \rho\right)$. For a special one-parameter subgroup

$$
\lambda: \mathbb{C}^{*} \rightarrow \mathrm{SL}\left(V_{m}\right)
$$

of $\operatorname{SL}\left(V_{m}\right)$, there exist integers $\gamma_{j}, j=0,1, \ldots, N_{m}$, and an orthonormal basis $\left\{s_{0}, s_{1}, \ldots, s_{N_{m}}\right\}$ for ( $V_{m}, \rho$ ) such that, for all $j$,

$$
\begin{equation*}
\lambda_{z} \cdot s_{j}=e^{z \gamma_{j}} s_{j}, \quad z \in \mathbb{C} \tag{4.2}
\end{equation*}
$$

where $\lambda_{z}:=\lambda\left(e^{z}\right)$. Recall that the subvariety $M_{m}$ in $\mathbb{P}^{*}\left(V_{m}\right)$ is the image of the Kodaira embedding $\Phi_{m}: M \hookrightarrow \mathbb{P}^{*}\left(V_{m}\right)$ defined by

$$
\begin{equation*}
\Phi_{m}(p)=\left(s_{0}(p): s_{1}(p): \cdots: s_{N_{m}}(p)\right), \quad p \in M \tag{4.3}
\end{equation*}
$$

where $\mathbb{P}^{*}\left(V_{m}\right)$ is identified with $\mathbb{P}^{N_{m}}(\mathbb{C})=\left\{\left(z_{0}: z_{1}: \cdots: z_{N_{m}}\right)\right\}$. Put $M_{m, t}:=\lambda_{t}\left(M_{m}\right)$ for each $t \in \mathbb{R}$. As in Section $2, \hat{M}_{m, t}:=\lambda_{t} \cdot \hat{M}_{m}$ is the nonzero point of $W_{m}^{*}$ sitting over the Chow point of the irreducible reduced cycle $M_{m, t}$ on $\mathbb{P}^{*}\left(V_{m}\right)$. Then (cf. [39, 1.4, 3.4.1])

$$
\begin{equation*}
\frac{d}{d t}\left(\log \left\|\hat{M}_{m, t}\right\|_{\mathrm{CH}(\rho)}\right)=(n+1) \int_{M} \frac{\sum_{j=0}^{N_{m}} \gamma_{j}\left|\lambda_{t} \cdot s_{j}\right|^{2}}{\sum_{j=0}^{N_{m}}\left|\lambda_{t} \cdot s_{j}\right|^{2}}\left(\Phi_{m}^{*} \lambda_{t}^{*} \omega_{\mathrm{FS}}\right)^{n} \tag{4.4}
\end{equation*}
$$

where $\omega_{\mathrm{FS}}$ is the Fubini-Study form $(\sqrt{-1} / 2 \pi) \partial \bar{\partial} \log \left(\sum_{j=0}^{N_{m}}\left|z_{j}\right|^{2}\right)$ on $\mathbb{P}^{*}\left(V_{m}\right)$, and we regard $\lambda_{t}$ as a linear transformation of $\mathbb{P}^{*}\left(V_{m}\right)$ induced by (4.2). Note that the term $\Phi_{m}^{*} \lambda_{t}^{*} \omega_{\mathrm{FS}}$ above is just $(\sqrt{-1} / 2 \pi) \partial \bar{\partial} \log \left(\sum_{j=0}^{N_{m}}\left|\lambda_{t} \cdot s_{j}\right|^{2}\right)$. Put $\Gamma:=2 \pi \sqrt{-1} \mathbb{Z}$. By setting

$$
\mathbb{C} / \Gamma=\{t+\sqrt{-1} \theta ; t \in \mathbb{R}, \theta \in \mathbb{R} /(2 \pi \mathbb{Z})\},
$$

we consider the complexified situation. Let $\eta: M \times \mathbb{C} / \Gamma \rightarrow \mathbb{P}^{*}\left(V_{m}\right)$ be the map sending each $(p, t+\sqrt{-1} \theta)$ in $M \times \mathbb{C} / \Gamma$ to $\lambda_{t+\sqrt{-1} \theta} \cdot \Phi_{m}(p)$ in $\mathbb{P}^{*}\left(V_{m}\right)$. For simplicity, we put

$$
Q:=\frac{\sum_{j=0}^{N_{m}} \gamma_{j} e^{2 t \gamma_{j}}\left|s_{j}\right|^{2}}{\sum_{j=0}^{N_{m}} e^{2 t \gamma_{j}}\left|s_{j}\right|^{2}}\left(=\frac{\sum_{j=0}^{N_{m}} \gamma_{j}\left|\lambda_{t} \cdot s_{j}\right|^{2}}{\sum_{j=0}^{N_{m}}\left|\lambda_{t} \cdot s_{j}\right|^{2}}\right) .
$$

We further put $z:=t+\sqrt{-1} \theta$. For the time being, on the total complex manifold $M \times$ $\mathbb{C} / \Gamma$, the $\partial$-operator and the $\bar{\partial}$-operator will be written simply as $\partial$ and $\bar{\partial}$ respectively, while on $M$, they will be denoted by $\partial_{M}$ and $\bar{\partial}_{M}$ respectively. Then

$$
\eta^{*} \omega_{\mathrm{FS}}=\Phi_{m}^{*} \lambda_{t}^{*} \omega_{\mathrm{FS}}+\frac{\sqrt{-1}}{2 \pi}\left(\partial_{M} Q \wedge d \bar{z}+d z \wedge \bar{\partial}_{M} Q\right)+\frac{\sqrt{-1}}{4 \pi} \frac{\partial Q}{\partial t} d z \wedge d \bar{z}
$$

For $0 \neq r \in \mathbb{R}$, we consider the 1 -chain $I_{r}:=[0, r]$, where $[0, r]$ means the 1-chain $-[r, 0]$ if $r<0$. Let $\mathrm{pr}: \mathbb{C} / \Gamma \rightarrow \mathbb{R}$ be the mapping sending each $t+\sqrt{-1} \theta$ to $t$. We now put $B_{r}:=\operatorname{pr}^{*} I_{r}$. Then $\int_{M \times B_{r}} \eta^{*} \omega_{\mathrm{FS}}^{n+1}$ is nothing but

$$
(n+1) \int_{0}^{r} d t \int_{M}\left(\frac{\partial Q}{\partial t} \Phi_{m}^{*} \lambda_{t}^{*} \omega_{\mathrm{FS}}^{n}+\frac{\sqrt{-1}}{\pi} \bar{\partial}_{M} Q \wedge \partial_{M} Q \wedge n \Phi_{m}^{*} \lambda_{t}^{*} \omega_{\mathrm{FS}}^{n-1}\right)
$$

$$
=\int_{0}^{r} \frac{d^{2}}{d t^{2}}\left(\log \left\|\hat{M}_{m, t}\right\|_{\mathrm{CH}(\rho)}\right) d t=\left.\frac{d}{d t}\left(\log \left\|\hat{M}_{m, t}\right\|_{\mathrm{CH}(\rho)}\right)\right|_{t=0} ^{t=r}
$$

and by assuming $r \geq 0$, we obtain the following convexity formula:

Theorem 4.5.

$$
\left.\frac{d}{d t}\left(\log \left\|\hat{M}_{m, t}\right\|_{\mathrm{CH}(\rho)}\right)\right|_{t=0} ^{t=r}=\int_{M \times B_{r}} \eta^{*} \omega_{\mathrm{FS}}^{n+1} \geq 0 .
$$

Remark 4.6. Besides special one-parameter subgroups of $\operatorname{SL}\left(V_{m}\right)$, we also consider a little more general smooth path $\lambda_{t}, t \in \mathbb{R}$, in $\operatorname{GL}\left(V_{m}\right)$ written explicitly by

$$
\lambda_{t} \cdot s_{j}=e^{t \gamma_{j}+\delta_{j}} s_{j}, \quad j=0,1, \ldots, N_{m},
$$

where $\gamma_{j}, \delta_{j} \in \mathbb{R}$ are not necessarily rational. In this case also, we easily see that the formula (4.4) and Theorem 4.5 are still valid.

## 5. Proof of Theorem $\mathbf{A}$

The statement of Theorem A is divided into "if" part, "only if" part, and the uniqueness part. We shall prove these three parts separately.

Proof of "if" part. Let $\omega \in \mathcal{S}$ be a critical metric relative to $T$. Then by Definition 2.6, in terms of the Hermitian metric defined in (2.4), there exists an admissible normal basis $\left\{s_{0}, s_{1}, \ldots, s_{N_{m}}\right\}$ for $V_{m}$ of index $b$ such that the associated function $E_{\omega, b}$ has a constant value $C$ on $M$. By operating $(\sqrt{-1} / 2 \pi) \partial \bar{\partial} \log$ on the identity $E_{\omega, b}=C$, we have

$$
\begin{equation*}
\Phi_{m}^{*} \omega_{\mathrm{FS}}=m \omega . \tag{5.1}
\end{equation*}
$$

Besides the Hermitian metric defined in (2.4), we shall now define another Hermitian metric on $V_{m}$. By the identification $V_{m} \cong \mathbb{C}^{N_{m}}$ via the basis $\left\{s_{0}, s_{1}, \ldots, s_{N_{m}}\right\}$, the standard Hermitian metric on $\mathbb{C}^{N_{m}}$ induces a Hermitian metric $\rho$ on $V_{m}$. As a maximal compact subgroup of $G_{m}$, we choose $\left(G_{m}\right)_{c}$ as in Section 2 by using the metric defined in (2.4). Then the Hermitian metric $\rho$ is also preserved by the $\left(G_{m}\right)_{c}$-action on $V_{m}$. Let

$$
\lambda: \mathbb{C}^{*} \rightarrow G_{m}
$$

be a special one-parameter subgroup of $G_{m}$. By the notation $l(k, i)$ as in Definition 2.3, we put $s_{k, i}:=s_{l(k, i)}$. If necessary, replacing $\left\{s_{0}, s_{1}, \ldots, s_{N_{m}}\right\}$ by another admissible normal basis for $V_{m}$ of the same index $b$, we may assume without loss of generality that there exist integers $\gamma_{k, i}, i=1,2, \ldots, n_{k}$, satisfying

$$
\begin{equation*}
\lambda_{t} \cdot s_{k, i}=e^{t \gamma_{k, i}} s_{k, i}, \quad t \in \mathbb{C} \tag{5.2}
\end{equation*}
$$

where $\lambda_{t}:=\lambda\left(e^{t}\right)$ is as in (4.2), and the equality $\sum_{i=1}^{n_{k}} \gamma_{k, i}=0$ is required to hold for every $k$. Put $\gamma_{k, i}=\gamma_{l(k, i)}$ for simplicity. Then by (4.4) and (5.1),

$$
\begin{aligned}
& \frac{d}{d t}\left(\log \left\|\hat{M}_{m, t}\right\|_{\mathrm{CH}(\rho)}\right)_{\mid t=0}=(n+1) \int_{M} \frac{\sum_{j=0}^{N_{m}} \gamma_{j}\left|s_{j}\right|^{2}}{\sum_{j=0}^{N_{m}}\left|s_{j}\right|^{2}}\left(\Phi_{m}^{*} \omega_{\mathrm{FS}}\right)^{n} \\
& =(n+1) m^{n} \int_{M} \frac{\sum_{j=0}^{N_{m}} \gamma_{j}\left|s_{j}\right|_{h^{m}}^{2}}{\sum_{j=0}^{N_{m}}\left|s_{j}\right|_{h^{m}}^{2}} \omega^{n}=(n+1) m^{n} \int_{M} \frac{\sum_{k=1}^{\nu_{m}}\left(\sum_{i=1}^{n_{k}} \gamma_{k, i}\left|s_{i}\right|_{h^{m}}^{2}\right.}{E_{\omega, b}} \omega^{n} \\
& =\frac{(n+1) m^{n}}{C} \int_{M} \sum_{k=1}^{\nu_{m}}\left(\sum_{i=1}^{n_{k}} \gamma_{k, i}\left|s_{i}\right|_{h^{m}}^{2}\right) \omega^{n}=\frac{(n+1) m^{n}}{C} \sum_{k=1}^{\nu_{m}} b_{k}\left(\sum_{i=1}^{n_{k}} \gamma_{k, i}\right)=0 .
\end{aligned}
$$

Note also that, by Theorem 4.5, we have $c:=\left(d^{2} / d t^{2}\right)\left(\log \left\|\hat{M}_{m, t}\right\|_{\mathrm{CH}(\rho)}\right)_{t t=0} \geq 0$.
CASE 1. If $c$ is positive, then $\lim _{t \rightarrow-\infty}\left\|\hat{M}_{m, t}\right\|_{\mathrm{CH}(\rho)}=+\infty=\lim _{t \rightarrow+\infty}\left\|\hat{M}_{m, t}\right\|_{\mathrm{CH}(\rho)}$, and in particular $\lambda\left(\mathbb{C}^{*}\right) \cdot \hat{M}_{m}$ is closed.

CASE 2. If $c$ is zero, then by applying Theorem 4.5 infinitesimally, we see that $\lambda\left(\mathbb{C}^{*}\right)$ preserves the subvariety $M_{m}$ in $\mathbb{P}^{*}\left(V_{m}\right)$, and moreover by

$$
\frac{d}{d t}\left(\log \left\|\hat{M}_{m, t}\right\|_{\mathrm{CH}(\rho)}\right)_{\mid t=0}=0
$$

the isotropy representation of $\lambda\left(\mathbb{C}^{*}\right)$ on the complex line $\mathbb{C} \hat{M}_{m}$ is trivial. Hence, $\lambda\left(\mathbb{C}^{*}\right) \cdot \hat{M}_{m}$ is a single point, and in particular closed.

Thus, these two cases together with Theorem 3.2 show that the subvariety $M_{m}$ of $\mathbb{P}^{*}\left(V_{m}\right)$ is stable relative to $T$, as required.

Remark 5.3. About the one-parameter subgroup $\left\{\lambda_{t} ; t \in \mathbb{R}\right\}$ of $G_{m}$, we consider a more general situation that $\gamma_{k, i}$ in (5.2) are just real numbers which are not necessarily rational. The above computation together with Remark 4.6 shows that, even in this case, $(d / d t)_{t=0}\left(\log \left\|\hat{M}_{m, t}\right\|_{\mathrm{CH}(\rho)}\right)$ vanishes.

Proof of "only if" part. Assume that the subvariety $M_{m}$ in $\mathbb{P}^{*}\left(V_{m}\right)$ is stable relative to $T$. Take a Hermitian metric $\rho$ for $V_{m}$ such that $V\left(\chi_{k}\right) \perp V\left(\chi_{l}\right)$ for $k \neq l$. For this $\rho$, we consider the associated Chow norm. Since the orbit $G_{m} \cdot \hat{M}_{m}$ is closed in $W_{m}$, the Chow norm restricted to this orbit attains an abosolute minimum. Hence, for some $g_{0} \in G_{m}$,

$$
0 \neq\left\|g_{0} \cdot \hat{M}_{m}\right\|_{\mathrm{CH}(\rho)} \leq\left\|g \cdot \hat{M}_{m}\right\|_{\mathrm{CH}(\rho)}, \quad \text { for all } g \in G_{m}
$$

By choosing an admissible normal basis $\left\{s_{0}, s_{1}, \ldots, s_{N_{m}}\right\}$ for ( $V_{m} ; \rho$ ) of index $(1,1, \ldots, 1)$, we identify $V_{m}$ with $\mathbb{C}^{N_{m}}=\left\{\left(z_{0}, z_{1}, \ldots, z_{N_{m}}\right)\right\}$. Then $\operatorname{SL}\left(V_{m}\right)$ is identi-
fied with $\operatorname{SL}\left(N_{m}+1 ; \mathbb{C}\right)$. Let $\mathfrak{g}_{m}$ be the Lie subalgebra of $\mathfrak{s l}\left(N_{m}+1 ; \mathbb{C}\right)$ associated to the Lie subgroup $G_{m}$ of $\operatorname{SL}\left(N_{m}+1 ; \mathbb{C}\right)$. We can now write $g_{0}=\kappa^{\prime} \cdot \exp \{\operatorname{Ad}(\kappa) D\}$ for some $\kappa, \kappa^{\prime} \in\left(G_{m}\right)_{c}$ and a real diagonal matrix $D$ in $\mathfrak{g}_{m}$. By $\left\|\exp \{\operatorname{Ad}(\kappa) D\} \cdot \hat{M}_{m}\right\|_{\mathrm{CH}(\rho)}=$ $\left\|g_{0} \cdot \hat{M}_{m}\right\|_{\mathrm{CH}(\rho)}$, we have
(5.4) $\left\|\exp \{\operatorname{Ad}(\kappa) D\} \cdot \hat{M}_{m}\right\|_{\mathrm{CH}(\rho)} \leq\left\|\exp \{t \operatorname{Ad}(\kappa) A\} \cdot \exp \{\operatorname{Ad}(\kappa) D\} \cdot \hat{M}_{m}\right\|_{\mathrm{CH}(\rho)}, t \in \mathbb{R}$,
for every real diagonal matrix $A$ in $\mathfrak{g}_{m}$. For $j=0,1, \ldots, N_{m}$, we write the $j$-th diagonal element of $A$ and $D$ above as $a_{j}$ and $d_{j}$, respectively. Put $c_{j}:=\exp d_{j}$ and $s_{j}^{\prime}:=\kappa^{-1} \cdot s_{j}$. Then $\left\{s_{0}^{\prime}, s_{1}^{\prime}, \ldots, s_{N_{m}}^{\prime}\right\}$ is again an admissible normal basis for $\left(V_{m}, \rho\right)$ of index $(1,1, \ldots, 1)$. By the notation in Definition 2.3, we rewrite $s_{j}^{\prime}, a_{j}, c_{j}, z_{j}$ as $s_{k, i}^{\prime}, a_{k, i}, c_{k, i}, z_{k, i}$ by

$$
s_{k, i}^{\prime}:=s_{l(k, i)}^{\prime}, \quad a_{k, i}:=a_{l(k, i)}, \quad c_{k, i}:=c_{l(k, i)}, \quad z_{k, i}:=z_{l(k, i)},
$$

where $k=1,2, \ldots, \nu_{m}$ and $i=1,2, \ldots, n_{k}$. By (5.4), the derivative at $t=0$ of the right-hand side of (5.4) vanishes. Hence by (4.4) together with Remark 4.6, fixing an arbitrary real diagonal matrix $A$ in $\mathfrak{g}_{m}$, we have

$$
\begin{equation*}
\int_{M} \frac{\sum_{k=1}^{\nu_{m}} \sum_{i=1}^{n_{k}} a_{k, i} c_{k, i}^{2}\left|s_{k, i}^{\prime}\right|^{2}}{\sum_{k=1}^{\nu_{m}} \sum_{i=1}^{n_{k}} c_{k, i}^{2}\left|s_{k, i}^{\prime}\right|^{2}} \Phi_{m}^{*}\left(\Theta^{n}\right)=0 \tag{5.5}
\end{equation*}
$$

where we set $\Theta:=(\sqrt{-1} / 2 \pi) \partial \bar{\partial} \log \left(\sum_{k=1}^{\nu_{m}} \sum_{i=1}^{n_{k}} c_{k, i}^{2}\left|z_{k, i}\right|^{2}\right)$. Let $k_{0} \in\left\{1,2, \ldots, \nu_{m}\right\}$ and let $i_{1}, i_{2} \in\left\{1,2, \ldots, n_{k}\right\}$ with $i_{1} \neq i_{2}$. Using Kronecker's delta, we specify the real diagonal matrix $A$ by setting

$$
a_{k, i}=\delta_{k k_{0}}\left(\delta_{i i_{1}}-\delta_{i i_{2}}\right), \quad k=1,2, \ldots, \nu_{m} ; i=1,2, \ldots, n_{k}
$$

Apply (5.5) to this $A$, and let ( $i_{1}, i_{2}$ ) run through the set of all pairs of two distinct elements in $\left\{1,2, \ldots, n_{k}\right\}$. Then there exists a positive constant $b_{k}>0$ independent of the choice of $i$ in $\left\{1,2, \ldots, n_{k}\right\}$ such that

The following identity (5.7) allows us to define (cf. [39]) a Hermitian metric $h_{\mathrm{FS}}$ on $L^{m}$ by

$$
\begin{equation*}
|s|_{h_{\mathrm{FS}}}^{2}:=\frac{\left(N_{m}+1\right)}{c_{1}(L)^{n}[M]} \frac{\sum_{k=1}^{\nu_{m}} \sum_{i=1}^{n_{k}}\left|\left(s, s_{k, i}^{\prime}\right)_{\rho}\right|^{2}\left|s_{k, i}^{\prime}\right|^{2}}{\sum_{k=1}^{\nu_{m}} \sum_{i=1}^{n_{k}} c_{k, i}^{2}\left|s_{k, i}^{\prime}\right|^{2}}, \quad s \in V_{m} . \tag{5.7}
\end{equation*}
$$

Then for this Hermitian metric, it is easily seen that

$$
\begin{equation*}
\sum_{j=0}^{N_{m}}\left|c_{j} s_{j}^{\prime}\right|_{h \mathrm{FS}}^{2}=\sum_{k=1}^{\nu_{m}} \sum_{i=1}^{n_{k}}\left|c_{k, i} s_{k, i}^{\prime}\right|_{h_{\mathrm{FS}}}^{2}=\frac{N_{m}+1}{c_{1}(L)^{n}[M]} \tag{5.8}
\end{equation*}
$$

By operating $(\sqrt{-1} / 2 \pi) \partial \bar{\partial} \log$ on both sides of (5.8), we obtain $\Phi_{m}^{*} \Theta=c_{1}\left(L^{m} ; h_{\mathrm{FS}}\right)$. We now set $h:=\left(h_{\mathrm{FS}}\right)^{1 / m}$ and $\omega:=c_{1}(L ; h)$. Then

$$
\omega=\frac{1}{m} \Phi_{m}^{*} \Theta
$$

Put $s_{k, i}^{\prime \prime}:=c_{k, i} s_{k, i}^{\prime}$, and as in Definition 2.3, we write $s_{k, i}^{\prime \prime}$ as $s_{l(k, i)}^{\prime \prime}$. Then by (5.8), we have the equality $\sum_{j=0}^{N_{m}}\left|s_{j}^{\prime \prime}\right|_{h^{m}}^{2}=\left(N_{m}+1\right) / c_{1}(L)^{n}[M]$. Moreover, in terms of the Hermitian metric defined in (2.4), the equality (5.6) is interpreted as

$$
\left\|s_{k, i}^{\prime \prime}\right\|_{L^{2}}^{2}=b_{k}, \quad k=1,2, \ldots, \nu_{m} ; i=1,2, \ldots, n_{k}
$$

while by this together with (5.8) above, we obtain $\sum_{k=1}^{\nu_{m}} n_{k} b_{k}=N_{m}+1$, as required.

Proof of uniqueness. Let $\omega=c_{1}(L ; h)$ and $\omega^{\prime}=c_{1}\left(L ; h^{\prime}\right)$ be critical metrics relative to $T$, and let $\left\{s_{j} ; j=0,1, \ldots, N_{m}\right\}$ and $\left\{s_{j}^{\prime} ; j=0,1, \ldots, N_{m}\right\}$ be respectively the associated admissible normal bases for $V_{m}$ of index $b$. We use the notation in Definition 2.3. Then

$$
E_{\omega, b}:=\sum_{k=1}^{\nu_{m}} \sum_{i=1}^{n_{k}}\left|s_{k, i}\right|_{h^{m}}^{2} \quad \text { and } \quad E_{\omega^{\prime}, b}:=\sum_{k=1}^{\nu_{m}} \sum_{i=1}^{n_{k}}\left|s_{k, i}^{\prime}\right|_{h^{\prime m}}^{2}
$$

take the same constant value $C:=\left(N_{m}+1\right) / c_{1}(L)^{n}[M]$ on $M$. Note here that, by operating $(\sqrt{-1} / 2 \pi) \partial \bar{\partial} \log$ on both of these identities, we obtain

$$
m \omega=\frac{\sqrt{-1}}{2 \pi} \partial \bar{\partial} \log \left(\sum_{k=1}^{\nu_{m}} \sum_{i=1}^{n_{k}}\left|s_{k, i}\right|^{2}\right) \quad \text { and } \quad m \omega^{\prime}=\frac{\sqrt{-1}}{2 \pi} \partial \bar{\partial} \log \left(\sum_{k=1}^{\nu_{m}} \sum_{i=1}^{n_{k}}\left|s_{k, i}^{\prime}\right|^{2}\right) .
$$

If necessary, we replace each $s_{k, i}$ by $\zeta_{k} s_{k, i}$ for a suitable complex number $\zeta_{k}$, independent of $i$, of absolute value 1 . Then for each $k=1,2, \ldots, \nu_{m}$, we may assume that there exists a matrix $g^{(k)}=\left(g_{i \hat{\imath}}^{(k)}\right) \in \mathrm{GL}\left(n_{k} ; \mathbb{C}\right)$ satisfying

$$
s_{k, \hat{\imath}}^{\prime}=\sum_{i=1}^{n_{k}} s_{k, i} g_{i \hat{\imath}}^{(k)},
$$

where $i$ and $\hat{\imath}$ always run through the integers in $\left\{1,2, \ldots, n_{k}\right\}$. Then the matrix $g^{(k)}$ above is written as $\kappa^{(k)} \cdot\left(\exp A^{(k)}\right) \cdot\left(\kappa^{\prime(k)}\right)^{-1}$ for some real diagonal matrix $A^{(k)}$ and

$$
\kappa^{(k)}=\left(\kappa_{i \hat{\imath}}^{(k)}\right) \quad \text { and } \quad \kappa^{\prime(k)}=\left(\kappa_{i \hat{\imath}}^{\prime(k)}\right)
$$

in $\operatorname{SU}\left(n_{k}\right)$. Let $a_{i}^{(k)}$ be the $i$-th diagonal element of $A^{(k)}$. For each $\hat{\imath}$, we put $\tilde{s}_{k, \hat{\imath}}:=\sum_{i=1}^{n_{k}} s_{k, i} \kappa_{i \hat{\imath}}^{(k)}$ and $\tilde{s}_{k, \hat{\imath}}^{\prime}:=\sum_{i=1}^{n_{k}} s_{k, i}^{\prime} \kappa_{i \hat{\imath}}^{\prime}{ }^{(k)}$. If necessary, we replace the bases
$\left\{s_{k, 1}, s_{k, 2}, \ldots, s_{k, n_{k}}\right\}$ and $\left\{s_{k, 1}^{\prime}, s_{k, 2}^{\prime}, \ldots, s_{k, n_{k}}^{\prime}\right\}$ for $V\left(\chi_{k}\right)$ by the bases $\left\{\tilde{s}_{k, 1}, \tilde{s}_{k, 2}, \ldots\right.$, $\left.\tilde{s}_{k, n_{k}}\right\}$ and $\left\{\tilde{s}_{k, 1}^{\prime}, \tilde{s}_{k, 2}^{\prime}, \ldots, \tilde{s}_{k, n_{k}}^{\prime}\right\}$, respectively. Then we may assume, from the beginning, that

$$
s_{k, i}^{\prime}=\left\{\exp a_{i}^{(k)}\right\} s_{k, i}, \quad i=1,2, \ldots, n_{k} .
$$

We now set $\tau_{k, i}:=s_{k, i} / \sqrt{b_{k}}$, and the Hermitian metric for $V_{m}$ defined in (2.4) will be denoted by $\rho$. Then $\left\{\tau_{k, i} ; k=1,2, \ldots, \nu_{m}, i=1,2, \ldots, n_{k}\right\}$ is an admissible normal basis of index $(1,1, \ldots, 1)$ for $\left(V_{m}, \rho\right)$. Let $\left\{\lambda_{t} ; t \in \mathbb{C}\right\}$ be the smooth one-parameter family of elements in $\operatorname{GL}\left(V_{m}\right)$ defined by

$$
\lambda_{t} \cdot \tau_{k, i}=\left\{\exp \left(t a_{i}^{(k)}\right)\right\} \sqrt{b_{k}} \tau_{k, i}, \quad k=1,2, \ldots, \nu_{m} ; i=1,2, \ldots, n_{k}
$$

Put $\hat{M}_{m, t}:=\lambda_{t} \cdot \hat{M}_{m}, 0 \leq t \leq 1$. Then by Remark 4.6 applied to the formula (4.4), the derivative $\mathfrak{d}(t):=(d / d t)\left(\log \left\|\hat{M}_{m, t}\right\|_{\mathrm{CH}(\rho)}\right) /(n+1)$ at $t \in[0,1]$ is expressible as

$$
\int_{M} \frac{\sum_{k=1}^{\nu_{m}} \sum_{i=1}^{n_{k}} a_{i}^{(k)}\left|\lambda_{t} \cdot \tau_{k, i}\right|^{2}}{\sum_{k=1}^{\nu_{m}} \sum_{i=1}^{n_{k}}\left|\lambda_{t} \cdot \tau_{k, i}\right|^{2}}\left\{\frac{\sqrt{-1}}{2 \pi} \partial \bar{\partial} \log \left(\sum_{k=1}^{\nu_{m}} \sum_{i=1}^{n_{k}}\left|\lambda_{t} \cdot \tau_{k, i}\right|^{2}\right)\right\}^{n} .
$$

Hence at $t=0$, we see that

$$
\mathfrak{d}(0)=\int_{M} \sum_{k=1}^{\nu_{m}} \sum_{i=1}^{n_{k}}\left\{\frac{a_{i}^{(k)}\left|s_{k, i}\right|_{h^{m}}^{2}}{C}\right\}(m \omega)^{n}=\frac{m^{n}}{C} \sum_{k=1}^{\nu_{m}}\left\{b_{k} \sum_{i=1}^{n_{k}} a_{i}^{(k)}\right\},
$$

while at $t=1$ also, we obtain

$$
\mathfrak{d}(1)=\int_{M} \sum_{k=1}^{\nu_{m}} \sum_{i=1}^{n_{k}}\left\{\frac{a_{i}^{(k)}\left|s_{k, i}^{\prime}\right|_{h^{\prime m}}^{2}}{C}\right\}\left(m \omega^{\prime}\right)^{n}=\frac{m^{n}}{C} \sum_{k=1}^{\nu_{m}}\left\{b_{k} \sum_{i=1}^{n_{k}} a_{i}^{(k)}\right\} .
$$

Thus, $\mathfrak{d}(0)$ coincides with $\mathfrak{d}(1)$, while by Remark 4.6, we see from Theorem 4.5 that $\left(d^{2} / d t^{2}\right)\left\{\log \left\|\hat{M}_{m, t}\right\|_{\mathrm{CH}(\rho)}\right\} \geq 0$ on $[0,1]$. Hence, for all $t \in[0,1]$,

$$
\frac{d^{2}}{d t^{2}}\left\{\log \left\|\hat{M}_{m, t}\right\|_{\mathrm{CH}(\rho)}\right\}=0, \quad \text { on } M
$$

By Remark 4.6, the formula in Theorem 4.5 shows that $\lambda_{t}, t \in[0,1]$, belong to $H$ up to a positive scalar multiple. Since $\lambda_{1}$ commutes with $T$, the uniqueness follows, as required.

## 6. Proof of Theorem B

Throughout this section, we assume that the first Chern class $c_{1}(L)_{\mathbb{R}}$ admits an extremal Kähler metric $\omega_{0}=c_{1}\left(L ; h_{0}\right)$. Then by a theorem of Calabi [3], the identity
component $K$ of the group of isometries of $\left(M, \omega_{0}\right)$ is a maximal compact connected subgroup of $H$, and we obtain $\omega_{0} \in \mathcal{S}_{K}$ by the notation in the introduction.

Definition 6.1. For a $K$-invariant Kähler metric $\omega \in \mathcal{S}_{K}$ on $M$ in the class $c_{1}(L)_{\mathbb{R}}$, we choose a Hermitian metric $h$ on $L$ such that $\omega=c_{1}(L ; h)$. Then the power series in $q$ given by the right-hand side of (2.8) will be denoted by $\Psi(\omega, q)$. Given $\omega$ and $q$, the power series $\Psi(\omega, q)$ is independent of the choice of $h$.

Let $\mathcal{D}_{0}$ be the Lichnérowicz operator as defined in [3], (2.1), for the extremal Kähler manifold $\left(M, \omega_{0}\right)$. Then by $\mathcal{V} \in \mathfrak{k}$, the operator $\mathcal{D}_{0}$ preserves the space $\mathcal{F}$ of all real-valued smooth $K$-invariant functions $\varphi$ such that $\int_{M} \varphi \omega_{0}^{n}=0$. Hence, we regard $\mathcal{D}_{0}$ just as an operator $\mathcal{D}_{0}: \mathcal{F} \rightarrow \mathcal{F}$, and the kernel in $\mathcal{F}$ of this restricted operator will be denoted simply by $\operatorname{Ker} \mathcal{D}_{0}$. Then $\operatorname{Ker} \mathcal{D}_{0}$ is a subspace of $\mathcal{K}_{\omega_{0}}$, and we have an isomorphism

$$
\begin{equation*}
e_{0}: \operatorname{Ker} \mathcal{D}_{0} \cong \mathfrak{z}, \quad \varphi \leftrightarrow e_{0}(\varphi):=\operatorname{grad}_{\omega_{0}}^{\mathbb{C}} \varphi \tag{6.2}
\end{equation*}
$$

By the inner product (, $)_{\omega_{0}}$ defined in the introduction, we write $\mathcal{F}$ as an orthogonal direct sum $\operatorname{Ker} \mathcal{D}_{0} \oplus \operatorname{Ker} \mathcal{D}_{0}^{\perp}$. We then consider the orthogonal projection

$$
P: \mathcal{F}\left(=\operatorname{Ker} \mathcal{D}_{0} \oplus \operatorname{Ker} \mathcal{D}_{0}^{\perp}\right) \rightarrow \operatorname{Ker} \mathcal{D}_{0}
$$

Now, starting from $\omega(0):=\omega_{0}$, we inductively define a Hermitian metric $h(k)$, a Kähler metric $\omega(k):=c_{1}(L ; h(k)) \in \mathcal{S}_{K}$, and a vector field $\mathcal{Y}(k) \in \sqrt{-1} \mathfrak{z}, k=1,2, \ldots$, by

$$
\left\{\begin{array}{l}
h(k):=h(k-1) \exp \left(-q^{k} \varphi_{k}\right)  \tag{6.3}\\
\omega(k)=\omega(k-1)+\frac{\sqrt{-1}}{2 \pi} q^{k} \partial \bar{\partial} \varphi_{k} \\
\mathcal{Y}(k)=\mathcal{Y}(k-1)+\sqrt{-1} q^{k+2} e_{0}\left(\zeta_{k}\right)
\end{array}\right.
$$

for appropriate $\varphi_{k} \in \operatorname{Ker} \mathcal{D}_{0}^{\perp}$ and $\zeta_{k} \in \operatorname{Ker} \mathcal{D}_{0}$, where $\omega(k)$ and $\mathcal{Y}(k)$ are required to satisfy the condition (2.8) with $l$ replaced by $k$. We now set $g(k):=\exp ^{\mathbb{C}} \mathcal{Y}(k)$. Then

$$
\begin{aligned}
& \{h(k) \cdot g(k)\}^{-m} h(k)^{m}\left\{Z(q, \omega(k) ; \mathcal{Y}(k))-C_{q}\right\} \\
& =\frac{n!}{m^{n}}\left\{\sum_{j=0}^{N_{m}}\left|s_{j}\right| h(k)^{m}\right\}-C_{q}\left\{g(k) \cdot h(k)^{-m}\right\} h(k)^{m} \\
& =\Psi(\omega(k), q)-C_{q} h(k)^{m}\left\{\left(\exp ^{\mathbb{C}} \mathcal{Y}(k)\right) \cdot h(k)^{-m}\right\} \\
& =\Psi(\omega(k), q)-C_{q}\left\{1+h(k) \frac{\mathcal{Y}(k)}{q} \cdot h(k)^{-1}+R(\mathcal{Y}(k) ; h(k))\right\},
\end{aligned}
$$

where $C_{q}=1+\sum_{k=0}^{\infty} \alpha_{k} q^{k+1}$ is a power series in $q$ with real coefficients $\alpha_{k}$ spec-
ified later, and the last term $R(\mathcal{Y}(k) ; h(k)):=h(k)^{m} \sum_{j=2}^{\infty}\left\{\mathcal{Y}(k)^{j} / j!\right\} \cdot h(k)^{-m}$ will be taken care of as a higher order term in $q$. Consider the truncated term $C_{q, l}=$ $1+\sum_{k=0}^{l} \alpha_{k} q^{k+1}$. Put

$$
\Xi\left(\omega(k), \mathcal{Y}(k), C_{q, k}\right):=\Psi(\omega(k), q)-C_{q, k}\left\{1-\frac{\mathcal{Y}(k)}{q} \cdot \log h(k)+R(\mathcal{Y}(k) ; h(k))\right\}
$$

for each $k$. Then, in terms of $\omega(k), \mathcal{Y}(k)$ and $C_{q, k}$, the condition (2.8) with $l$ replaced by $k$ is just the equivalence

$$
\begin{equation*}
\Xi\left(\omega(k), \mathcal{Y}(k), C_{q, k}\right) \equiv 0, \quad \text { modulo } q^{k+2} \tag{6.4}
\end{equation*}
$$

We shall now define $\omega(k), \mathcal{Y}(k)$ and $C_{q, k}$ inductively in such a way that the condition (6.4) is satisfied. If $k=0$, then we set $\omega(0)=\omega_{0}, \mathcal{Y}(0)=\sqrt{-1} q^{2} \mathcal{V} / 2$ and $C_{q, 0}=1+\alpha_{0} q$, where we put $\alpha_{0}:=\left\{2 c_{1}(L)^{n}[M]\right\}^{-1}\left\{\int_{M} \sigma_{\omega} \omega^{n}+2 \pi F(\mathcal{V})\right\}$ for $\omega \in \mathcal{S}_{K}$. This $\alpha_{0}$ is obviously independent of the choice of $\omega$ in $\mathcal{S}_{K}$. Then, modulo $q^{2}$,

$$
\begin{aligned}
& \Psi(\omega(k), q)-C_{q, 0}\left\{1-\frac{\mathcal{Y}(0)}{q} \cdot \log h(0)+R(\mathcal{Y}(0) ; h(0))\right\} \\
& \equiv\left(1+\frac{\sigma_{\omega_{0}}}{2} q\right)-\left(1+\alpha_{0} q\right)\left\{1-q h_{0}^{-1} \sqrt{-1} \frac{\mathcal{V}}{2} \cdot h_{0}\right\} \\
& \equiv\left(1+\frac{\sigma_{\omega_{0}}}{2} q\right)-\left(1+\alpha_{0} q\right)\left\{1+\left(\frac{\sigma_{\omega_{0}}}{2}-\alpha_{0}\right) q\right\} \equiv 0,
\end{aligned}
$$

and we see that (6.4) is true for $k=0$. Here, the equality $h_{0}^{-1} \sqrt{-1}(\mathcal{V} / 2) \cdot h_{0}=\alpha_{0}-$ ( $\sigma_{\omega_{0}} / 2$ ) follows from a routine computation (see for instance [23]).

Hence, let $l \geq 1$ and assume (6.4) for $k=l-1$. It then suffices to find $\varphi_{l}, \zeta_{l}$ and $\alpha_{l}$ satisfying (6.4) for $k=l$. Put $\mathcal{Y}_{l}:=\sqrt{-1} e_{0}\left(\zeta_{l}\right)$. For each $\left(\varphi_{l}, \zeta_{l}, \alpha_{l}\right) \in \operatorname{Ker} \mathcal{D}_{0}^{\perp} \times$ $\operatorname{Ker} \mathcal{D}_{0} \times \mathbb{R}$, we consider

$$
\begin{aligned}
\Phi\left(q ; \varphi_{l}, \zeta_{l}, \alpha_{l}\right):= & \Psi\left(\omega(l-1)+\frac{\sqrt{-1}}{2 \pi} q^{l} \partial \bar{\partial} \varphi_{l}, q\right)-\left(C_{q, l-1}+\alpha_{l} q^{l+1}\right) \\
\times & \left\{1-\left(\frac{\mathcal{Y}(l-1)}{q}+q^{l+1} \mathcal{Y}_{l}\right) \cdot \log \left\{h(l-1) \exp \left(-q^{l} \varphi_{l}\right)\right\}\right. \\
& \left.+R\left(\frac{\mathcal{Y}(l-1)}{q}+q^{l+1} \mathcal{Y}_{l} ; h(l-1) \exp \left(-q^{l} \varphi_{l}\right)\right)\right\}
\end{aligned}
$$

By the induction hypothesis, $\Xi\left(\omega(l-1), \mathcal{Y}(l-1), C_{q, l-1}\right) \equiv 0$ modulo $q^{l+1}$. Since $\Phi(q ; 0,0,0)=\Xi\left(\omega(l-1), \mathcal{Y}(l-1), C_{q, l-1}\right)$, we have

$$
\Phi(q ; 0,0,0) \equiv u_{l} q^{l+1}, \quad \text { modulo } q^{l+2}
$$

for some real-valued $K$-invariant smooth function $u_{l}$ on $M$. Let $\left(\varphi_{l}, \zeta_{l}, \alpha_{k}\right) \in \operatorname{Ker} \mathcal{D}_{0}^{\perp} \times$ $\operatorname{Ker} \mathcal{D}_{0} \times \mathbb{R}$. Since $\varphi_{k}$ is $K$-invariant, by $\mathcal{V} \in \mathfrak{k}$, we see that $\sqrt{-1} \mathcal{V} \varphi_{k}$ is a real-valued
function on $M$. Note also that $\mathcal{Y}(0)=(\sqrt{-1} \mathcal{V} / 2) q^{2}$. Then the variation formula for the scalar curvature (see for instance [3, (2.5)]) shows that, modulo $q^{l+2}$,

$$
\begin{aligned}
& \Phi\left(q ; \varphi_{l}, \zeta_{l}, \alpha_{l}\right) \\
& \equiv \Phi(q ; 0,0,0)+\frac{q^{l+1}}{2}\left(-\mathcal{D}_{0}+\sqrt{-1} \mathcal{V}\right) \varphi_{l}-\alpha_{l} q^{l+1}+q^{l+1} h_{0}^{-1}\left(\mathcal{Y}_{l} \cdot h_{0}\right)-\frac{\sqrt{-1}}{2} \mathcal{V} \varphi_{l} q^{l+1} \\
& \equiv\left\{u_{l}-\mathcal{D}_{0} \frac{\varphi_{l}}{2}-\alpha_{l}-\hat{F}_{m}\left(\mathcal{Y}_{l}\right)+e_{0}^{-1}\left(\sqrt{-1} \mathcal{Y}_{l}\right)\right\} q^{l+1}
\end{aligned}
$$

where we put $\hat{F}(\mathcal{Y}):=\left\{c_{1}(L)^{n}[M]\right\}^{-1} 2 \pi F(\sqrt{-1} \mathcal{Y})$ for each $\mathcal{Y} \in \sqrt{-1} \mathfrak{z}$. By setting $\mu_{l}:=\left\{c_{1}(L)^{n}[M]\right\}^{-1}\left(\int_{M} u_{l} \omega_{0}^{n}\right)$, we write $u_{l}$ as a sum

$$
u_{l}=\mu_{l}+u_{l}^{\prime}+u_{l}^{\prime \prime},
$$

where $u_{l}^{\prime}:=(1-P)\left(u_{l}-\mu_{l}\right) \in \operatorname{Ker} \mathcal{D}_{0}^{\perp}$ and $u_{l}^{\prime \prime}:=P\left(u_{l}-\mu_{l}\right) \in \operatorname{Ker} \mathcal{D}_{0}$. Now, let $\varphi_{l}$ be the unique element of $\operatorname{Ker} \mathcal{D}_{0}^{\perp}$ such that $\mathcal{D}_{0}\left(\varphi_{l} / 2\right)=u_{l}^{\prime}$. Moreover, we put

$$
\zeta_{l}:=u_{l}^{\prime \prime} \quad \text { and } \quad \alpha_{l}:=\mu_{l}-\hat{F}\left(\mathcal{Y}_{l}\right)
$$

Then by $\mathcal{Y}_{l}=\sqrt{-1} e_{0}\left(\zeta_{l}\right)=\sqrt{-1} e_{0}\left(u_{l}^{\prime \prime}\right)$, we obtain

$$
\begin{aligned}
\Phi\left(q ; \varphi_{l}, \zeta_{l}, \alpha_{l}\right) & \equiv\left\{\mu_{l}+u_{l}^{\prime}+u_{l}^{\prime \prime}-\mathcal{D}_{0} \frac{\varphi_{l}}{2}-\alpha_{l}-\hat{F}_{m}\left(\mathcal{Y}_{l}\right)+e_{0}^{-1}\left(\sqrt{-1} \mathcal{Y}_{l}\right)\right\} q^{l+1} \\
& \equiv\left\{u_{l}^{\prime \prime}+e_{0}^{-1}\left(\sqrt{-1} \mathcal{Y}_{l}\right)\right\} q^{l+1} \equiv 0, \quad \bmod q^{l+2}
\end{aligned}
$$

as required. Write $\sqrt{-1} \mathcal{V} / 2$ as $\mathcal{Y}_{0}$ for simplicity. Now, for the real Lie subalgebra $\mathfrak{b}$ of $\mathfrak{z}$ generated by $\mathcal{Y}_{k}, k=0,1,2, \ldots$, its complexification $\mathfrak{b}^{\mathbb{C}}$ in $\mathfrak{z}^{\mathbb{C}}$ generates a complex Lie subgroup $B^{\mathbb{C}}$ of $Z^{\mathbb{C}}$. Then it is easy to check that the algebraic subtorus $T$ of $Z^{\mathbb{C}}$ obtained as the closure of $B^{\mathbb{C}}$ in $Z^{\mathbb{C}}$ has the required properties.

Remark 6.5. In Theorem B, assume that $\omega_{0}$ is a Kähler metric of constant scalar curvature, and moreover that the actions $\rho_{m(\nu)}, \nu=1,2, \ldots$, coincide (cf. [26, (2.3)]) for all sufficiently large $\nu$. Then by [26], the trivial group $\{1\}$ can be chosen as the algebraic subtorus $T$ above of $Z^{\mathbb{C}}$.
