ON THE IDEAL CLASS GROUPS OF RAY CLASS FIELDS OF ALGEBRAIC NUMBER FIELDS

HIROYUKI OSADA

(Received June 8, 2001)

For an algebraic number field k, $C(k)$ and $\tilde{k}$ denote the ideal class group and the Hilbert class field of k, respectively. For an abelian group G and an integer m, G^m means the subgroup of G consisting of m-th powers of the elements of G. Let $h(k)$, $R(k)$ and $D(k)$ be the class number, the regulator and the absolute value of the discriminant of k, respectively. For an integer $m > 1$, k_m denotes the class field of k corresponding to ray modulo m. Let ζ_m be a primitive m-th root of unity. Let q be a prime and k/Q be a real cyclic extension of degree q. Let m be the conductor of k. In the paper [5], we showed that $C(Q(\zeta_m + \zeta_m^{-1}))$ has a subgroup which is isomorphic to $C(k)^q$. In this paper we generalize the above result in Theorem 1. And we show that for any given integer $n > 1$, there exist infinitely many mutually prime positive integers m such that
(1) m has at most two different prime factors and any prime factor of m is congruent to $1 \pmod 4$,
(2) $C(Q(\zeta_m + \zeta_m^{-1}))$ has a subgroup which is isomorphic to $Z/A_m Z$ for some integer $A_m > n$
(Corollary of Theorem 3). Further we give some applications of the following Theorem 1.

Theorem 1. *Let L/k be an abelian extension and K be a subfield of L such that K/k is an extension of degree n. Then $C(L)$ has a subgroup which is isomorphic to $C(K)^{nh(k)}$.*

Proof. By Galois theory, we have the following exact sequence

$$\mathrm{Gal}(\tilde{L}/L) \to \mathrm{Gal}(\tilde{K}/K) \to \mathrm{Gal}(L \cap \tilde{K}/K) \to 0.$$

Hence by class field theory, we have the following exact sequence

$$C(L)^{N_{L/K}} \to C(K)^f \to \mathrm{Gal}(L \cap \tilde{K}/K) \to 0,$$

where $N_{L/K}$ is the norm map from $C(L)$ to $C(K)$. Now we write the class groups additively. Let $x \in C(K)$ and $G = \mathrm{Gal}(K/k)$. Since $h(k) \cdot C(k) = 0$, we have that

$\sum_{\sigma\in G}\sigma(h(k)x)=0$. Hence $nh(k)x = nh(k)x - \sum_{\sigma\in G}\sigma(h(k)x) = \sum_{\sigma\in G}(1-\sigma)h(k)x$. Since $L\cap\tilde{K}/k$ is an abelian extension, the group G acts trivially on $\mathrm{Gal}(L\cap\tilde{K}/K)$ by conjugation. From the G-homomorphism f maps each $(1-\sigma)h(k)x$ to 0, it follows that $f(nh(k)x)=0$. By exactness, we see that the image $C(L)$ contains $nh(k)x$. Since $N_{L/K}(C(L))$ has a subgroup $C(K)^{nh(k)}$, we see that $C(L)$ has a subgroup which is isomorphic to $C(K)^{nh(k)}$. This completes the proof. □

EXAMPLE. Let $K = Q(\sqrt{145})$ and $L = Q(\zeta_{145}+\zeta_{145}^{-1})$. By $C(K)$ is isomorphic to $Z/4Z$ and Theorem 1, we see that $C(L)$ has a subgroup which is isomorphic to $Z/2Z$. And we see that $L\cap\tilde{K} = Q(\sqrt{5},\sqrt{29})$.

Lemma 1. *For any given integer $r>1$, let q_i $(1\leqq i\leqq r-1)$ be odd primes such that $q_1<q_2<\cdots<q_{r-1}$. Let $n>q_1$ be an integer and $m=(2nq_1q_2\cdots q_{r-1})^2+1$. If m is a square-free integer, then $C(Q(\sqrt{m}))$ has a subgroup which is isomorphic to Z/S_mZ for some integer $S_m>r$.*

Proof. Let $F = Q(\sqrt{m})$ and $u = 2nq_1q_2\cdots q_{r-1}$. Since $n>q_1$ and $q_1<q_2<\cdots<q_{r-1}$, we see that $q_1^r<u/2$. Since $m\equiv 1 \pmod{q_1}$, we have that $(q_1)=ßß'$ and $ß\neq ß'$, where ß and ß′ are prime ideals in F. Now we assume that $ß^s$ is a principal ideal in F for some positive integer s. Then there exist integers x and y such that

$$ß^s = \left(\frac{x+y\sqrt{m}}{2}\right) \quad \text{and} \quad x\equiv y \pmod 2.$$

Hence we have

$$q_1^s = \left|\frac{x^2-y^2m}{4}\right|,$$

that is,

$$\pm 4q_1^s = x^2-y^2m.$$

If $y=0$, then we have $x^2=4q_1^s$. Hence s is necessarily $2t$ for some integer t. Since $x=\pm 2q_1^t$, we have

$$ß^{2t} = (q_1^t) = ß^t ß'^t.$$

Therefore we have $ß=ß'$. This contradicts $ß\neq ß'$. Hence we have $y\neq 0$. Let x_0 be an integer and y_0 be the smallest positive integer satisfying

$$ß^s = \left(\frac{x_0+y_0\sqrt{m}}{2}\right),$$

that is,

$$ß^s = \left(\frac{\pm|x_0| + y_0\sqrt{m}}{2}\right).$$

Let $\varepsilon = \pm u + \sqrt{m}$. Since ε are units of F, we have

$$ß^s = \left(\frac{(\pm|x_0| + y_0\sqrt{m})(\mp u + \sqrt{m})}{2}\right),$$

that is,

$$ß^s = \left(\frac{-|x_0|u + y_0 m \pm (|x_0| - y_0 u)\sqrt{m}}{2}\right).$$

From $||x_0| - y_0 u| > 0$ and the definition of y_0, we have

$$||x_0| - y_0 u| \geqq y_0.$$

Hence either $|x_0| - y_0 u \geqq y_0$ or $-|x_0| + y_0 u \geqq y_0$. So either

$$\pm 4q_1^s = x_0^2 - y_0^2 m \geqq y_0^2(u+1)^2 - y_0^2(u^2+1) = 2uy_0^2 \geqq 2u.$$

or

$$\pm 4q_1^s = x_0^2 - y_0^2 m \leqq y_0^2(u-1)^2 - y_0^2(u^2+1) = -2uy_0^2 \leqq -2u.$$

Therefore in each case $4q_1^s \geqq 2u$, that is, $q_1^s \geqq u/2$. If $r \geqq s$, then this contradicts $q_1^r < u/2$. So if $r \geqq s$, $ß^s$ is not a principal ideal in F. Now we assume that $t = S_m$ is the smallest positive integer such that $ß^t$ is a principal ideal in F. From the above argument, we see that $C(F)$ has a subgroup which is isomorphic to $Z/S_m Z$ for some integer $S_m > r$. This completes the proof. □

Lemma 2. *Let $G(n) = an^2 + bn + c$ be an irreducible polynomial with $a > 0$ and $c \equiv 1 \pmod 2$. Then there exist infinitely many integers n such that $G(n)$ has at most two prime factors (see Iwaniec* [2, Theorem]).

Theorem 2. *For any given integer $r > 1$, there exist infinitely many mutually prime positive integers m such that*

(1) *m has at most two different prime factors and any prime factor of m is congruent to* $1 \pmod 4$,

(2) *$C(Q(\sqrt{m}))$ has a subgroup which is isomorphic to $Z/S_m Z$ for some integer $S_m > r$.*

Proof. For any given integer $r > 1$, let $m = (2nq_1q_2\cdots q_{r-1})^2 + 1$, where $q_i (1 \leqq i \leqq r-1)$ are odd primes such that $q_1 < q_2 < \cdots < q_{r-1}$ and $n > q_1$ is an integer.

Then by Lemma 2, there exist infinitely many integers n such that m has at most two different prime factors. It is easy to see that any prime factor of m is congruent to 1 (mod 4). Hence by Lemma 1, we have this theorem. □

Theorem 3. *Let k be an algebraic number field. Then for any given integer $n > 1$, there exist infinitely many mutually prime positive integers m such that*
(1) *m has at most two different prime factors and any prime factor of m is congruent to* $1 \pmod 4$,
(2) *$C(k_m)$ has a subgroup which is isomorphic to $Z/A_m Z$ for some integer $A_m > n$.*

Proof. By Theorem 2, for any given integer $r > 1$, there exists a positive integer m such that
(1) m has at most two different prime factors and any prime factor of m is congruent to $1 \pmod 4$,
(2) $C(Q(\sqrt{m}))$ has a subgroup which is isomorphic to $Z/S_m Z$ for some integer $S_m > r$.
Let $F = Q(\sqrt{m})$, $(D(k), m) = 1$ and $K = kF$. Then $C(K)$ has a subgroup which is isomorphic to $C(F)$. By k_m contains K, $[K : k] = 2$ and Theorem 1, we see that $C(k_m)$ has a subgroup which is isomorohic to $C(K)^{2h(k)}$. Hence by Theorem 2, for any given integer $r > 1$, there exist infinitely many mutually prime positive integers m such that
(1) m has at most two different prime factors and any prime factor of m is congruent to $1 \pmod 4$,
(2) $C(k_m)$ has a subgroup which is isomorphic to $2h(k)(Z/S_m Z)$ for some integer $S_m > r$.
Let $r \geqq 2nh(k)$ for any given integer $n > 1$ and $2h(k)(Z/S_m Z) = Z/A_m Z$. Then we have $A_m > n$. Thus this theorem is proved. □

Putting $k = Q$ in Theorem 3, we have

Corollary. *For any given integer $n > 1$, there exist infinitely many mutually prime positive integers m such that*
(1) *m has at most two different prime factors and any prime factor of m is congruent to* $1 \pmod 4$,
(2) *$C(Q(\zeta_m + \zeta_m^{-1}))$ has a subgroup which is isomorphic to $Z/A_m Z$ for some integer $A_m > n$.*

Theorem 4. *Let k be an algebraic number field and $t > 1$ be an integer. Then for any given integer $n_i > 1$ $(1 \leqq i \leqq t)$, there exist infinitely many mutually prime positive integers $m_1, m_2, \ldots, m_t$ such that*
(1) *m_i has at most two different prime factors and any prime factor of m_i is congruent to* $1 \pmod 4$,

(2) *$C(k_{m_1 m_2 \cdots m_t})$ has a subgroup which is isomorphic to $\bigoplus_{i=1}^{t} Z/A_{m_i}Z$ for some integer $A_{m_i} > n_i$.*

Proof. By Theorem 2, for any given integer $r_i > 1$ $(1 \leqq i \leqq t)$, there exist mutually prime positive integers m_i such that
(1) m_i has at most two different prime factors and any prime factor of m_i is congruent to $1 \pmod 4$,
(2) $C(Q(\sqrt{m_i}))$ has a subgroup which is isomorphic to $Z/S_{m_i}Z$ for some integer $S_{m_i} > r_i$.
Let $F = Q(\sqrt{m_1}, \sqrt{m_2}, \ldots, \sqrt{m_t})$. Then $C(F)$ has a subgroup which is isomorphic to $\bigoplus_{i=1}^{t} Z/S_{m_i}Z$. Let $(D(k), m_i) = 1$ $(1 \leqq i \leqq t)$ and $K = kF$. Then $C(K)$ has a subgroup which is isomorphic to $C(F)$. By $k_{m_1 m_2 \cdots m_t}$ contains $K, [K : k] = 2^t$ and Theorem 1, we see that $C(k_{m_1 m_2 \cdots m_t})$ has a subgroup which is isomorphic to $C(K)^{2^t h(k)}$. Hence by Theorem 2, for any given integer $r_i > 1$ $(1 \leqq i \leqq t)$, there exist infinitely many mutually prime positive integers $m_1, m_2, \ldots, m_t$ such that
(1) m_i has at most two different prime factors and any prime factor of m_i is congruent to $1 \pmod 4$,
(2) $C(k_{m_1 m_2 \cdots m_t})$ has a subgroup which is isomorphic to $\bigoplus_{i=1}^{t} 2^t h(k)(Z/S_{m_i}Z)$ for some integer $S_{m_i} > r_i$.
Let $r_i \geqq 2^t n_i h(k)$ for any given integer $n_i > 1$ and $2^t h(k)(Z/S_{m_i}Z) = Z/A_{m_i}Z$. Then we have $A_{m_i} > n_i$. Thus we have this theorem. □

Putting $k = Q$ in Theorem 4, we have

Corollary. *Let $t > 1$ be an integer. Then for any given integer $n_i > 1$ $(1 \leqq i \leqq t)$, there exist infinitely many mutually prime positive integers $m_1, m_2, \ldots, m_t$ such that*
(1) *m_i has at most two different prime factors and any prime factor of m_i is congruent to* $1 \pmod 4$,
(2) *$C(Q(\zeta_{m_1 m_2 \cdots m_t} + \zeta_{m_1 m_2 \cdots m_t}^{-1}))$ has a subgroup which is isomorphic to $\bigoplus_{i=1}^{t} Z/A_{m_i}Z$ for some integer $A_{m_i} > n_i$.*

Lemma 3. *Let $n > 1$ be an integer. For given finite sets S_1, S_2, S_3 of primes satisfying $S_i \cap S_j = \phi$ if $i \neq j$, there exist infinitely many imaginary (resp. real) quadratic number fields F such that*
(a) *the ideal class group of F has a subgroup which is isomorphic to $Z/nZ \oplus Z/nZ$ (resp. Z/nZ),*

$$\text{(b) all primes contained in } S_i \begin{cases} \text{are decomposed in } F & (i = 1), \\ \text{remain prime in } F & (i = 2), \\ \text{are ramified in } F & (i = 3) \end{cases}$$

(*see Yamamoto* [8, Theorem 2]).

Theorem 5. *Let k be an algebraic number field and A be any finite abelian group. Then there exist infinitely many mutually prime positive square-free integers t such that*
(1) $t \equiv 1 \pmod 4$,
(2) *$C(k_t)$ has a subgroup which is isomorphic to A.*

Proof. Let A be any finite abelian group. Then A is isomorphic to $\bigoplus_{i=1}^{s} Z/n_i Z$ for some integers $n_i > 1$ and $s \geqq 1$. It suffices to prove this theorem for the case $s > 1$. By Lemma 3, for given integer n_i ($1 \leqq i \leqq s$), there exist mutually prime positive square-free integers m_i such that
(1) $m_i \equiv 1 \pmod 4$,
(2) $C(Q(\sqrt{m_i}))$ has a subgroup which is isomorphic to $Z/2^s h(k) n_i Z$.
Now we put $t = m_1 m_2 \cdots m_s$. Let $F = Q(\sqrt{m_1}, \sqrt{m_2}, \ldots, \sqrt{m_s})$. Let $(D(k), D(F)) = 1$ and $K = kF$. Then $C(K)$ has a subgroup which is isomorphic to $C(F)$ and $C(F)$ has a subgroup which is isomorphic to $\bigoplus_{i=1}^{s} Z/2^s h(k) n_i Z$. By k_t contains K, $[K : k] = 2^s$ and Theorem 1, we see that $C(k_t)$ has a subgroup which is isomorphic to $C(K)^{2^s h(k)}$. Hence $C(k_t)$ has a subgroup which is isomorphic to $\bigoplus_{i=1}^{s} Z/n_i Z$. Therefore by Lemma 3, we have this theorem. □

Putting $k = Q$ in Theorem 5, we have

Corollary. *Let A be any finite abelian group. Then there exist infinitely many mutually prime positive square-free integers t such that*
(1) $t \equiv 1 \pmod 4$,
(2) *$C(Q(\zeta_t + \zeta_t^{-1}))$ has a subgroup which is isomorphic to A.*

REMARK. $k_m \cap k_n = \tilde{k}$, if $(m, n) = 1$.

The Brauer-Siegel theorem. *Let k be a normal algebraic number field of degree n over Q. Then*

$$\frac{\log(h(k)R(k))}{\log\sqrt{D(k)}} \to 1 \quad \textit{as} \quad \frac{n}{\log D(k)} \to 0$$

(*see Lang* [3, Chapter IX]).

Theorem 6. *Let k be a totally imaginary algebraic number field and $h(k) = 2^s$ for an integer $s \geqq 0$. Let p be an odd prime such that $p \equiv 3 \pmod 4$. Then there exist infinitely many primes p such that for any given integer $n > 1$, $C(k_p)$ has a subgroup which is isomorphic to $C(Q(\sqrt{-p}))$ with $h(Q(\sqrt{-p})) > n$.*

Proof. We assume that $D(k) < p$. Let $F = Q(\sqrt{-p})$ and $K = kF$. Then $C(K)$ has a subgroup which is isomorphic to $C(F)$. By k_p contains K, $[K : k] = 2$ and

Theorem 1, $C(k_p)$ has a subgroup which is isomorphic to $C(K)^{2h(k)}$. From $h(k) = 2^s$ for an integer $s \geqq 0$ and $2 \nmid h(F)$, we see that $C(F)^{2h(k)} = C(F)$. Therefore $C(k_p)$ has a subgroup which is isomorphic to $C(F)$. On the other hand, we see that $R(F) = 1$ and $D(F) = p$. Hence by the Brauer-Siegel theorem, we have

$$\frac{\log h(F)}{\log \sqrt{p}} \to 1 \quad \text{as} \quad p \to \infty.$$

So by Dirichlet's theorem on prime numbers in arithmetic progressions, there exist infinitely many primes p such that for any given integer $n > 1$, $C(k_p)$ has a subgroup which is isomorphic to $C(F)$ with $h(F) > n$. This completes the proof. □

Lemma 4. *There exist infinitely many primes p such that $p | h(Q(\zeta_p))$, that is, $p | B_{2s}$ for some integer s $(2 \leqq 2s \leqq p - 3)$, where B_{2s} are the Bernoulli numbers* (*see* [1]).

Lemma 5. *Let p be an odd prime such that $p | h(Q(\zeta_p))$. Let f_p be the number of s satisfying $p | B_{2s}$ $(2 \leqq 2s \leqq p - 3)$. Then $C(Q(\zeta_p))$ has a subgroup which is isomorphic to $\bigoplus_{i=1}^{f_p} Z/pZ$ (see Ribet* [6, Main Theorem]).

Theorem 7. *Let k be a totally imaginary algebraic number field and p be an odd prime such that $p | h(Q(\zeta_p))$. Let f_p be as in* Lemma 5. *Then there exist infinitely many primes p such that $C(k_p)$ has a subgroup which is isomorphic to $\bigoplus_{i=1}^{f_p} Z/pZ$.*

Proof. Let $D(k) < p$ and $h(k) < p$. Let $F = Q(\zeta_p)$ and $K = kF$. Then $C(K)$ has a subgroup which is isomorphic to $C(F)$. By k_p contains K, $[K : k] = p - 1$ and Theorem 1, $C(k_p)$ has a subgroup which is isomorphic to $C(K)^{(p-1)h(k)}$. So by Lemma 4, Lemma 5 and $(h(k)(p-1), p) = 1$, there exist infinitely many primes p such that $C(k_p)$ has a subgroup which is isomorphic to $\bigoplus_{i=1}^{f_p} Z/pZ$. This completes the proof. □

Lemma 6. *Let p be an odd prime such that $p \equiv 2^{a+1} + 1 \pmod{2^{a+2}}$ with $a \geqq 1$. Let k and k_0 be the subfields of $Q(\zeta_p)$ such that $[k : Q] = 2^{a+1}$ and $[k_0 : Q] = 2^a$, respectively. And let $h_1 = h(k)/h(k_0)$. Then*

$$\frac{\log h_1}{2^{a-1} \log p} \to 1 \quad \textit{as} \quad p \to \infty.$$

Proof. Let $R(k) = R$ and $R(k_0) = R_0$. Then it is known that $R = 2^{2^a - 1} R_0$. By $D(k) = p^{2^{a+1}-1}$, $D(k_0) = p^{2^a - 1}$ and the Brauer-Siegel theorem, we have

$$\frac{\log(h(k)R)}{\log \sqrt{D(k)}} \to 1 \quad \text{and} \quad \frac{\log(h(k_0)R_0)}{\log \sqrt{D(k_0)}} \to 1 \quad \text{as} \quad p \to \infty.$$

Since

$$\frac{\log(h(k)R)}{\log\sqrt{D(k)}} = \frac{\log h_1}{\log\sqrt{D(k)}} + \frac{\log(h(k_0)R_0)}{(2^a - 1/2)\log p} + \frac{(2^a - 1)\log 2}{(2^a - 1/2)\log p}$$

and

$$\frac{\log(h(k_0)R_0)}{(2^a - 1/2)\log p} = \frac{\log(h(k_0)R_0)}{\log\sqrt{D(k_0)}} \cdot \frac{2^a - 1}{2^{a+1} - 1},$$

it follows that

$$\frac{\log h_1}{2^{a-1}\log p} \to 1 \quad \text{as} \quad p \to \infty.$$

This completes the proof. □

Theorem 8. *Let k be a totally imaginary algebraic number field and $h(k) = 2^s$ for an integer $s \geqq 0$. Let p be an odd prime such that $p \equiv 2^{a+1} + 1 \pmod{2^{a+2}}$ with $a \geqq 1$. Let F be the subfield of $Q(\zeta_p)$ such that $[F : Q] = 2^{a+1}$. Then for any given integer $n > 1$, there exist infinitely many primes p such that $C(k_p)$ has a subgroup which is isomorphic to $C(F)$ with $h(F) > n$.*

Proof. Let $D(k) < p$ and $K = kF$. Then $C(K)$ has a subgroup which is isomorphic to $C(F)$. By k_p contains K, $[K : k] = 2^{a+1}$ and Theorem 1, $C(k_p)$ has a subgroup which is isomorphic to $C(K)^{2^{a+1}h(k)}$. By genus theory, we see that $2 \nmid h(F)$. From $h(k) = 2^s$ for an integer $s \geqq 0$ and $2 \nmid h(F)$, we see that $C(F)^{2^{a+1}h(k)} = C(F)$. Hence $C(k_p)$ has a subgroup which is isomorphic to $C(F)$. By Lemma 6 and Dirichlet's theorem on prime numbers in arithmetic progressions, for any given integer $n > 1$, there exist infinitely many primes p such that $C(k_p)$ has a subgroup which is isomorphic to $C(F)$ with $h(F) > n$. This completes the proof. □
